

File M/G/1 avec priorités sans préemption

(R.G. Miller Jr. Priority Queues 1960)

la file 1 est prioritaire sur la file 2 mais n'interrupt pas le service d'une personne non-prioritaire.

File résultante $A_t = A_t^{(1)} + A_t^{(2)}$, taux $\lambda = \lambda_1 + \lambda_2$

service résultant $S = S^{(N)}$ avec $N: \Omega \rightarrow \{1, 2\}$, $P(N=1) = \frac{\lambda_1}{\lambda_1 + \lambda_2}$, $P(N=2) = \frac{\lambda_2}{\lambda_1 + \lambda_2}$.

$$E(S) = \frac{\rho}{\mu} \text{ avec } \rho = \rho_1 + \rho_2 = \frac{\lambda_1}{\mu_1} + \frac{\lambda_2}{\mu_2}, \quad L_S(z) = \frac{\lambda_1}{\lambda} L_{S^{(1)}}(z) + \frac{\lambda_2}{\lambda} L_{S^{(2)}}(z).$$

On introduit une chaîne de Markov induite Q_{t_n} où t_n est l'instant de départ de la n^e personne

$Q_{t_n} = (Q_{t_n}^{(1)}, Q_{t_n}^{(2)})$, et on détermine la loi de $Q_{\infty} \equiv Q_{t_{\infty}}$.

Loi conjointe des deux files

Théorème :

$$G_{Q_{\infty}}(z, s) = \frac{1 - \rho}{s [z - L_{S^{(1)}}(\lambda_1(1-z) + \lambda_2(1-s))]} \left\{ z [s L_{S^{(N)}} - L_{S^{(2)}}] \Big|_{\lambda_1(1-z) + \lambda_2(1-s)} + \frac{[z L_{S^{(2)}} - s L_{S^{(1)}}] \Big|_{\lambda_1(1-z) + \lambda_2(1-s)}}{s - L_{S^{(2)}}(s^*)} \left[s \frac{\lambda_1 L_{B^{(1)}}(\lambda_2(1-s)) + \lambda_2 L_{S^{(2)}}(s^*)}{\lambda_1 + \lambda_2} - L_{S^{(2)}}(s^*) \right] \right\}$$

où $B^{(1)}$ est la période d'activité du serveur avec la file 1

$$s^* = \lambda_1 [1 - L_{B^{(1)}}(\lambda_2(1-s))] + \lambda_2(1-s)$$

$$L_{B^{(1)}}(\lambda) = L_{S^{(1)}}[\lambda + \lambda_1(1 - L_{B^{(1)}}(\lambda))]$$

avec
$$\Delta_K^* = \sum_{i=1}^{K-1} \frac{\lambda_i}{l_K} L_S^{(i)}(\lambda + l_K (1 - \Delta_K^*)) = L_{\bar{S}^{(K-1)}}(\lambda + l_K (1 - \Delta_K^*))$$
 où $\bar{S}^{(K-1)}$ est le service résultant d'une file à $(K-1)$ types

Ainsi $\Delta_K^* = L_{\bar{B}^{(K-1)}}(\lambda)$ où $\bar{B}^{(K-1)}$ est la période d'activité du serveur avec les types $1, 2, \dots, K-1$.

$$G_i^{(2)}(s) = \left[\frac{\lambda_1}{\lambda_1 + \mu_2 + \lambda_2(1-s)} \right]^i G_0^{(2)}(s), \quad i \geq 0$$

De (E1) on déduit que $G_i^{(1)}(s)$ est de la forme $\alpha(s) \zeta_1^i + \beta(s) \zeta_2^i + \gamma(s) \left[\frac{\lambda_1}{\lambda_1 + \mu_2 + \lambda_2(1-s)} \right]^i$

(réurrence linéaire avec second membre suite géométrique \rightarrow solution particulière suite géo. de même type)

$$\zeta_1 < 1 < \zeta_2 : \text{ racines de } \mu_1 z^2 - [\lambda_1 + \mu_1 + \lambda_2(1-s)]z + \lambda_1 = 0$$

Pour que $G_i^{(1)}(s)$ reste borné lorsque $i \rightarrow +\infty$ il faut que $\beta = 0$.

On a donc $G_i^{(1)}(s) = \alpha(s) \zeta_1^i + \gamma(s) \left[\frac{\lambda_1}{\lambda_1 + \mu_2 + \lambda_2(1-s)} \right]^i$ avec $\zeta_1 = \frac{\lambda_1 + \mu_1 + \lambda_2(1-s) - \sqrt{[\lambda_1 + \mu_1 + \lambda_2(1-s)]^2 - 4\lambda_1\mu_1}}{2\mu_1}$

$$\begin{aligned} \text{or } \gamma(s) &= - \frac{\lambda_1 \mu_2 G_0^{(2)}(s)}{\lambda_1 \mu_1 \zeta_1 + (\mu_2 - \mu_1) \zeta_1 [\lambda_1 + \mu_2 + \lambda_2(1-s)]} \times \frac{\lambda_1 + \mu_2 + \lambda_2(1-s)}{\lambda_1} \\ &= - \frac{\mu_2 [\lambda_1 + \mu_2 + \lambda_2(1-s)]}{s [\lambda_1 \mu_1 + (\mu_2 - \mu_1)(\lambda_1 + \mu_2 + \lambda_2(1-s))]} G_0^{(2)}(s) \end{aligned}$$

En faisant comme si l'équation (E1) était prolongeable en $i \in \{0, 1\}$, on trouverait

• pour $i=1$: $-\mu_1 G_2^{(1)}(s) + [\lambda_1 + \mu_1 + \lambda_2(1-s)] G_1^{(1)}(s) - \lambda_1 G_0^{(1)}(s) = \frac{\mu_2}{s} G_1^{(2)}(s)$

soit, en comparant avec (E2) : $G_0^{(1)}(s) = \pi_{00}$

• pour $i=0$: $-\mu_1 G_1^{(1)}(s) + [\lambda_1 + \mu_1 + \lambda_2(1-s)] \underbrace{G_0^{(1)}(s)}_{\pi_{00}} - \lambda_1 G_{-1}^{(1)}(s) = \frac{\mu_2}{s} G_0^{(2)}(s)$

or, d'après (E4) : $\mu_1 G_1^{(1)}(s) = [\lambda_1 + \mu_2 + \lambda_2(1-s) - \frac{\mu_2}{s}] G_0^{(2)}(s) + [\lambda_1 + \lambda_2(1-s)] \pi_{00}$

d'où $G_{-1}^{(1)}(s) = \frac{1}{\lambda_1} [\mu_1 \pi_{00} - [\lambda_1 + \mu_2 + \lambda_2(1-s)] G_0^{(2)}(s)]$

Ainsi $\begin{cases} G_0^{(1)}(s) = \alpha(s) + \gamma(s) = \pi_{00} \\ G_{n-1}^{(1)}(s) = \frac{\alpha(s)}{\zeta_1} + \gamma(s) \frac{\lambda_1 + \mu_2 + \lambda_2(1-s)}{\lambda_1} = \frac{\mu_1 \pi_{00}}{\lambda_1} - \frac{\lambda_1 + \mu_2 + \lambda_2(1-s)}{\lambda_1} G_0^{(2)}(s) \end{cases}$

et alors
$$\| G_i^{(2)}(1) = \mathbb{P}(Q_{\infty}^{(1)} = i, N' = 2) = \frac{\lambda_2}{\lambda_1 + \mu_2} \left(\frac{\lambda_1}{\lambda_1 + \mu_2} \right)^i, i \geq 0$$

En sommant sur $i \geq 0$ on récupère
$$\mathbb{P}(N' = 2) = \frac{\lambda_2}{\mu_2} = \rho_2$$

(formule différente de la générale $\mathbb{P}(N' = 2) = \frac{\lambda_2}{\mu_2}$ car ici N'_t est le type du client en service alors qu'avant on avait affaire à N'_n : type du n^{e} client en service (ou juste sorti))

$$\| G_i^{(1)}(1) = \mathbb{P}(Q_{\infty}^{(1)} = i, N' = 1) = \frac{(\mu_1 - \lambda_1)[\mu_2(\lambda_1 - \mu_1 + \mu_2) + \lambda_2 \mu_1]}{\mu_1 \mu_2 (\lambda_1 - \mu_1 + \mu_2)} \rho_1^i - \frac{\lambda_2}{\lambda_1 - \mu_1 + \mu_2} \left(\frac{\lambda_1}{\lambda_1 + \mu_2} \right)^i, i \geq 1$$

En sommant sur $i \geq 1$ ($\mathbb{P}(Q_{\infty}^{(1)} = 0, N' = 1) = 0$) on récupère

$$\mathbb{P}(N' = 1) = \frac{\lambda_1 [\mu_2(\lambda_1 - \mu_1 + \mu_2) + \lambda_2 \mu_1]}{\mu_1 \mu_2 (\lambda_1 - \mu_1 + \mu_2)} = \frac{\lambda_1 \lambda_2}{\mu_1 \mu_2 (\lambda_1 - \mu_1 + \mu_2)} \Rightarrow \mathbb{P}(N' = 1) = \frac{\lambda_1}{\mu_1} = \rho_1$$

D'où $E(Q_{\infty}^{(1)}) = \sum_{i=1}^{\infty} i [G_i^{(1)}(1) + G_i^{(2)}(1)] \Rightarrow E[Q_{\infty}^{(1)}] = \frac{\lambda_1}{\mu_1 - \lambda_1} \left(1 + \frac{\lambda_2 \mu_1}{\mu_2^2} \right) = \rho_1 + \frac{\lambda_1}{2} \frac{\lambda_1 E(S_1^2) + \lambda_2 E(S_2^2)}{1 - \rho_1}$

En recommençant avec les autres fonctions génératrices $E(z^{Q_{\infty}^{(1)}}, Q_{\infty}^{(2)} = j, N' = \dots)$, on

obtiendrait $E[Q_{\infty}^{(2)}] = \rho_2 + \frac{\lambda_2}{\mu_1 - \lambda_1} \times \frac{\rho_1 + \rho_2 \mu_1 / \mu_2}{1 - \rho} = \rho_2 + \frac{\lambda_2}{2} \frac{\lambda_1 E(S_1^2) + \lambda_2 E(S_2^2)}{(1 - \rho_1)(1 - \rho)}$

(formules différentes du cas général (chaîne induite))

La fonction génératrice conjointe est donnée par

avec $\gamma(z) = \frac{\pi_{00} \mu_2 [\lambda_1 + \lambda_2 (1 - s) - \mu_2 s_1]}{\lambda_1 \mu_1 s + (\mu_2 - \mu_1) s [\lambda_1 + \lambda_2 (1 - s) + \mu_2] + \mu_2 (\mu_1 (1 - s_1) - \mu_2)}$

Après calculs : $G_{Q_{\infty}}(z, s) = \frac{(1 - \rho) \mu_1 (1 - 1/2)}{\lambda_1 (1 - z) + \lambda_2 (1 - s) + \mu_1 (1 - 1/2)} + \frac{G^{(2)}(s) [\lambda_1 + \lambda_2 (1 - z) + \mu_2] [\mu_1 (1 - 1/2) - \mu_2 (1 - 1/5)]}{[\lambda_1 (1 - z) + \lambda_2 (1 - s) + \mu_2] [\lambda_1 (1 - z) + \lambda_2 (1 - s) + \mu_1 (1 - 1/2)]}$

(voir R.G. Miller: Priority queues)

rem: $\frac{\mu_1 (1 - 1/2)}{\lambda_1 (1 - z) + \lambda_2 (1 - s) + \mu_1 (1 - 1/2)} = \frac{\mu_1 (1 - z)}{\mu_1 - (\lambda_1 + \mu_1 + \lambda_2 (1 - s)) z + \lambda_1 z^2} = \frac{1 - z}{(1 - 5_1 z)(1 - 5_2 z)}$ (peut peut-être aider ... !)
