At a mémoire de Michelle Schatzman, notre chère et regrettée collègue et amie.†

The purpose of this paper is to enhance a correspondence between the dynamics of the differential equations \( \dot{y}(t) = g(y(t)) \) on \( \mathbb{R}^d \) and those of the parabolic equations \( \dot{u} = \Delta u + f(x, u, \nabla u) \) on a bounded domain \( \Omega \). We give details on the similarities of these dynamics in the cases \( d = 1 \), \( d = 2 \) and \( d \geq 3 \) and in the corresponding cases \( \Omega = (0, 1) \), \( \Omega = \mathbb{T}^1 \) and \( \dim(\Omega) \geq 2 \) respectively. In addition to the beauty of such a correspondence, this could serve as a guideline for future research on the dynamics of parabolic equations.

Keywords: Finite- and infinite-dimensional dynamical systems; vector fields; scalar parabolic equation; Kupka–Smale property; genericity.

AMS Subject Classification: 35-02, 37-02, 35B05, 35B41, 35K57, 37C10, 37C20

1. Introduction

In this paper, we want to point out the similarities between the dynamics of vector fields in \( \mathbb{R}^d \) and those of reaction-diffusion equations on bounded domains. More precisely, we consider the following classes of equations.

∗Corresponding author
†The results of this paper have been presented at the Conference in honour of the 60th birthday of Michelle Schatzman. The second author would like to express her gratitude towards Michelle, who guided her first steps in the research in mathematics and was a true friend.
1.1. Class of vector fields

Let $d \geq 1$ and $r \geq 1$ and let $g \in C^r(\mathbb{R}^d, \mathbb{R}^d)$ be a given vector field. We consider the ordinary differential equation

$$\begin{align*}
    \dot{y}(t) &= g(y(t)) \quad t > 0 \\
    y(0) &= y_0 \in \mathbb{R}^d
\end{align*}$$

(1.1)

where $\dot{y}(t)$ denotes the time-derivative of $y(t)$.

Equation (1.1) defines a local dynamical system $T_g(t)$ on $\mathbb{R}^d$ by setting $T_g(t)y_0 = y(t)$. We assume that there exists $M > 0$ large enough such that

$$\forall y \in \mathbb{R}^d, \|y\| \geq M \Rightarrow \langle y|g(y) \rangle < 0.$$ 

This condition ensures that $T_g(t)$ is a global dynamical system. Moreover, the ball $B(0, M)$ attracts the bounded sets of $\mathbb{R}^d$. Therefore, $T_g(t)$ admits a compact global attractor $A_g$. The attractor $A_g$ contains the most interesting trajectories such as periodic, homoclinic and heteroclinic orbits and any $\alpha$- or $\omega$-limit set. Therefore, if one neglects the transient dynamics, the dynamics on $A_g$ is a good representation of the whole dynamics of $T_g(t)$.

1.2. Class of scalar parabolic equations

Let $d' \geq 1$ and let $\Omega$ be either a regular bounded domain of $\mathbb{R}^{d'}$, or the torus $\mathbb{T}^{d'}$. We choose $p > d'$ and $\alpha \in ((p + d')/2p, 1)$. We denote $X^\alpha \equiv D((\Delta_N)^\alpha)$ the fractional power space associated with the Laplacian operator $\Delta_N$ on $L^p(\Omega)$ with homogeneous Neumann boundary conditions. It is well known that $X^\alpha$ is continuously embedded in the Sobolev space $W^{2\alpha,p}(\Omega)$ and thus it is compactly embedded in $C^1(\Omega)$. Let $r \geq 1$ and $f \in C^r(\overline{\Omega} \times \mathbb{R} \times \mathbb{R}^{d'}, \mathbb{R})$. We consider the parabolic equation

$$\begin{align*}
    \dot{u}(x,t) &= \Delta u(x,t) + f(x, u(x,t), \nabla u(x,t)), \quad (x,t) \in \Omega \times (0, +\infty), \\
    \frac{\partial u}{\partial \nu}(x,t) &= 0, \quad (x,t) \in \partial \Omega \times (0, +\infty), \\
    u(x,0) &= u_0(x) \in X^\alpha,
\end{align*}$$

(1.2)

where $\dot{u}(t)$ is the time-derivative of $u(t)$.

Equation (1.2) defines a local dynamical system $S_f(t)$ on $X^\alpha$ (see [41]) by setting $S_f(t)u_0 = u(t)$. We assume moreover that there exist $c \in C^0(\mathbb{R}_+, \mathbb{R}_+)$, $\varepsilon > 0$ and

\text{To make the reading of this paper easier for the reader who is not familiar with dynamical systems theory or with the study of PDEs, we add a short glossary at the end of the paper.}
\( \kappa > 0 \) such that \( f \) satisfies
\[
\forall R > 0, \quad \forall \xi \in \mathbb{R}^d, \quad \sup_{(x,z) \in \Omega \times [-R,R]} |f(x, z, \xi)| \leq c(R)(1 + |\xi|^{2-\epsilon})
\]
and
\[
\forall z \in \mathbb{R}, \quad \forall x \in \Omega, \quad |z| \geq \kappa \Rightarrow zf(x, z, 0) < 0.
\]
Then, Eq. (1.2) defines a global dynamical system in \( X^\alpha \) which admits a compact global attractor \( A \) (see [73]).

The reader, which is not familiar with partial differential equations, may neglect all the technicalities about \( X^\alpha \), the Sobolev spaces and the parabolic equations in a first reading. The most important point is that \( S_f(t) \) is a dynamical system defined on an infinite-dimensional function space. Compared with the finite-dimensional case, new difficulties arise. For example, the existence of a compact global attractor requires compactness properties, coming here from the smoothing effect of (1.2).

We also mention that, even if the backward uniqueness property holds, backward trajectories do not exist in general for (1.2). The reader interested in the dynamics of (1.2) may consult [25, 41, 35, 73] or [79].

The purpose of this paper is to emphasize the different relationships between the dynamics of (1.1) and (1.2). The correspondence is surprisingly perfect. It can be summarized in Table 1. This correspondence has already been noticed for some of the properties of the table. We complete here the correspondence for all the known properties of the dynamics of the parabolic equation. Table 1 will be discussed in more details in Sec. 2 and, for cooperative systems, in Sec. 4. Some of the properties presented in the table concerning finite-dimensional dynamical systems are trivial, others are now well-known. However, the corresponding results for the parabolic equation are more involved and some of them are very recent. These properties are mainly based on Sturm–Liouville arguments and unique continuation properties for the parabolic equations as explained in Sec. 3. The study of the dynamics generated by vector fields in dimension \( d \geq 3 \) is still a subject of research. Taking into account the correspondence presented in Table 1 should give a guideline for research on the dynamics of the parabolic equations. Some examples of open questions are given in Sec. 5.

We underline that we only consider the dynamics on the compact global attractors. Hence, we deal with dynamical systems on compact sets. It is important to be aware of the fact that, even if the dimension of the compact global attractor \( A \) of the parabolic equation (1.2) is finite, it can be made as large as wanted by choosing a suitable function \( f \). This is true even if \( \Omega \) is one-dimensional. Therefore, all the possible properties of the dynamics of (1.2) do not come from the low dimension of \( A \) but from properties, which are very particular to the flow of the parabolic equations.

Finally, we remark that most of the results described here also hold in more general frames than (1.1) and (1.2). For example, \( \mathbb{R}^d \) could be replaced by a compact orientable manifold without boundary. We could also choose for (1.2) more general...

boundary conditions than Neumann ones, or less restrictive growing conditions for $f$. The domain $\Omega$ may be replaced by a bounded smooth manifold. Finally, notice that the case $\Omega = \mathbb{T}^d$ can be seen as $\Omega = (0, 1)^d$ with periodic boundary conditions.

2. Details and Comments about the Correspondence Table
We expect the reader to be familiar with the basic notions of the theory of dynamical systems and flows. Some definitions are briefly recalled in the glossary at the end
Similitude Between the Dynamics of ODEs and of Parabolic Equations

475

of this paper. For more precisions, we refer for example to [50, 57, 62, 81] or [85] for finite-dimensional dynamics and to [37, 41, 82] or [36] for the infinite-dimensional ones.

We would first like to give short comments and motivations concerning the properties appearing in Table 1. Notice that we do not deal in this section with the cooperative systems of ODEs. The properties of these systems are discussed in Sec. 4.

A generic property of the dynamics is a property satisfied by a countable intersection of open dense subsets of the considered class of dynamical systems. Generic dynamics represent the typical behavior of a class of dynamical systems. For finite-dimensional flows, we mainly consider classes of the form \((T_g(t))_{g \in C^1(R^d, R^d)}\). The parameter is the vector field \(g\), which belongs to the space \(C^1(R^d, R^d)\) endowed with either the classical \(C^1\) or the \(C^1\) Whitney topology. Notice that the question whether or not a property is generic for \(g \in C^r(R^d, R^d)\) for some \(r \geq 2\) may be much more difficult than \(C^1\) genericity. We will not discuss this problem here.

In some cases, we restrict the class of vector fields to subspaces of \(C^1(R^d, R^d)\) such as radially symmetric, gradient vector fields or cooperative systems. In a similar way, for infinite-dimensional dynamics, we consider families of the type \((S_f(t))_{f \in C^1(\Omega \times R \times R^d, R)}\), where \(C^1(\Omega \times R \times R^d, R)\) is endowed with either the classical \(C^1\) or the \(C^1\) Whitney topology. For some results, we restrict the class of nonlinearities \(f\) to homogeneous ones or to those, which are independent of the last variable \(\xi\).

Poincaré–Bendixson property and the convergence to an equilibrium or a periodic orbit are properties related to the following question: how simple are the \(\alpha\)- and \(\omega\)-limit sets of the trajectories? For vector fields, the restriction of the complexity of the limit sets may come from the restriction of freedom due to the low dimension of the flow. As mentioned above, there is no restriction on the dimension of the global attractor for the parabolic equations. The possible restrictions of the complexity of the limit sets come from particular properties of the parabolic equations, see Sec. 3.

Hyperbolicity of equilibria and periodic orbits, transversality of stable and unstable manifolds, Kupka–Smale and Morse–Smale properties are properties related to the question of stability of the local and global dynamics respectively. Morse–Smale property is the strongest one. It implies the structural stability of the global dynamics: if the dynamical system \(T_\bar{g}(t)\) satisfies the Morse–Smale property, then for \(\bar{g}\) close enough to \(g\), the dynamics of \(T_\bar{g}(t)\), restricted to its attractor \(A_\bar{g}\), are qualitatively the same as the ones of \(T_g(t)\) on \(A_g\), see [61, 63] and [62]. The same structural stability result holds for parabolic equations satisfying the Morse–Smale property, see [37, 36] and [60]. It is natural to wonder if almost all the dynamics satisfy these properties, that is if these properties are generic.

The fact that the knowledge of the equilibria and the periodic orbits implies the knowledge of the whole dynamics may be studied at different levels. Two equilibria or periodic orbits being given, can we know if they are connected or not by a heteroclinic orbit? Are two dynamics with the same equilibria and periodic orbits
equivalent? Is there a simple algorithm to determine the global dynamics from the position of the equilibria and the periodic orbits? These questions are among the rare dynamical questions coming from the study of partial differential equations and not from the study of vector fields. Indeed, for finite-dimensional dynamical systems, the answers, either positive or negative, are too simple. In contrast, such kinds of results are probably among the most amazing ones for the dynamics of the parabolic equations.

The persistent chaotic dynamics and the fact that the dimension of the attractor is equal to the largest dimension of the unstable manifolds, are related to the following question: how complicated may be the dynamics? In general, the dimension of the attractor of a dynamical system may be larger than the largest dimension of the unstable manifolds. The classes of systems, where these dimensions automatically coincide, are strongly constrained, which in some sense implies a simple behavior. On the contrary, chaotic dynamics have very complicated behavior. Chaotic dynamics may occur through several phenomena, and the notion of chaotic behavior depends on the authors. In this paper, “persistent chaotic dynamics” refers to the presence of a tranversal homoclinic orbit generating a Smale horseshoe (see [89]). The persistent chaotic dynamics provide complicated dynamics, which cannot be removed by small perturbations of the system. Such an open set of chaotic dynamics is a counterexample to the genericity of the Morse–Smale systems.

The question of the realization of vector fields in the parabolic equations is as follows: a vector field $g \in C^r(\mathbb{R}^d, \mathbb{R}^d)$ being given, can we find a function $f$ and an invariant manifold $M \subset L^p(\Omega)$ such that the dynamics of the parabolic equation (1.2) restricted to $M$ is equivalent to the dynamics generated by the vector field $g$? A positive answer to this question implies that the dynamics of the considered class of parabolic equations is at least as complicated as the dynamics of the considered class of vector fields. Such a realization result is very interesting since, on the opposite, the other properties stated in Table 1 roughly say that the dynamics of the parabolic equation (1.2) cannot be much more complicated than the ones of the corresponding class of finite-dimensional flows. One has to keep in mind that the manifold $M$, on which the finite-dimensional dynamics are realized, is not necessarily stable with respect to the dynamics of the parabolic equation. Typically, $M$ cannot be stable if the finite-dimensional system contains a stable periodic orbit, since all periodic orbits of (1.2) are unstable (see for example [45]).

Now, we give short comments and references for the correspondences stated in Table 1.

- $d = 1$ and $\Omega = (0, 1)$

The dynamics generated by a one-dimensional vector field is very simple. Its attractor consists in equilibrium points and heteroclinic orbits connecting two of them. The existence of these heteroclinic orbits is easily deduced from the positions of the equilibrium points. Moreover, these heteroclinic connections are trivially transversal. Finally, (1.1) is clearly a gradient system with associated Lyapunov functional $F(y) = -\int_0^y g(s)ds$. As a consequence, the Morse–Smale property is equivalent
to the hyperbolicity of all the equilibrium points, which holds for a generic one-dimensional vector field.

The dynamics $S_f(t)$ generated by (1.2) for $\Omega = (0, 1)$ is richer since its attractor may have a very large dimension. However, these dynamics satisfy similar properties. These similarities are mainly due to the constraints coming from the non-increase of the number of zeros of solutions of the linear parabolic equation (see Theorem 3.1). Zelenyak has proved in [97] that $S_f(t)$ admits an explicit Lyapunov function and thus that it is gradient. He also showed that the $\omega$-limit sets of the trajectories consist in single equilibrium points. In Proposition 3.2, we give a short proof of this result, due to Matano. The fact that the stable and unstable manifolds of equilibrium points always intersect transversally comes from Theorem 3.1 and the standard Sturm–Liouville theory. This property has been first proved by Henry in [40] and later by Angenent [2] in the weaker case of hyperbolic equilibria. As a consequence of the previous results, the Morse–Smale property is equivalent to the hyperbolicity of the equilibrium points and is satisfied by the parabolic equation on $(0, 1)$ generically with respect to $f$. The most surprising result concerning (1.2) on $\Omega = (0, 1)$ is the following one. Assuming that every equilibrium point is hyperbolic and that the equilibrium points $e_1, \ldots, e_p$ are known, one can say if two given equilibria $e_i$ and $e_j$ are connected or not by a heteroclinic orbit. This property has been proved by Brunovský and Fiedler in [12] for $f = f(u)$ and by Fiedler and Rocha in [21] in the general case. The description of the heteroclinic connections is obtained from the Sturm permutation which is a permutation generated by the respective positions of the values $e_i(0)$ and $e_i(1)$ of the equilibrium points at the endpoints of $\Omega = (0, 1)$. The importance of Sturm permutation has been first underlined by Fusco and Rocha in [28]. We also refer to the work of Wolfrum [96], which presents a very nice formalism for this property. Fiedler and Rocha showed in [23] that the Sturm permutation characterizes the global dynamics of (1.2) on $(0, 1)$. They proved in [22] that it is possible to give the exact list of all the permutations which are Sturm permutations for some nonlinearity $f$ and thus to give the list of all the possible dynamics of the parabolic equation on $(0, 1)$. The fact that the dimension of the attractor is equal to the largest dimension of the unstable manifolds has been shown by Rocha in [83]. The previous works of Jolly [46] and Brunovský [11] deal with the particular case $f \equiv f(u)$, but show a stronger result: the attractor can be embedded in a $C^1$ invariant graph of dimension equal to the largest dimension of the unstable manifolds. Finally, let us mention that it is easy to realize any one-dimensional flow in an invariant manifold of the semi-flow generated by the one-dimensional parabolic equation. For example, in the simplest case of Neumann boundary conditions as in (1.2), one can realize the flow of any vector field $g$ as the restriction of the dynamics of the equation $\dot{u} = \Delta u + g(u)$ to the subspace of spatially constant functions.

- $d = 2$ and $\Omega = \mathbb{T}^1$, general case

Even if they are richer than in the one-dimensional case, the flows generated by vector fields on $\mathbb{R}^2$ are constrained by the Poincaré–Bendixson property (see the
original works of Poincaré [67] and Bendixson [7] or any textbook on ordinary differential equations). In particular, this constraint precludes the existence of non-trivial non-wandering points in Kupka–Smale dynamics. Due to the low dimension of the dynamics, the stable and unstable manifolds of hyperbolic equilibria or periodic orbits always intersect transversally if either one of the manifolds corresponds to a periodic orbit or if the invariant manifolds correspond to two equilibrium points with different Morse indices. Moreover, there is no homoclinic trajectory for periodic orbits. Using these particular properties, Peixoto proved in [64] that the Morse–Smale property holds for a generic two-dimensional vector field.

The first correspondence between two-dimensional flows and the dynamics of the parabolic equation (1.2) on the circle $\Omega = T^1$ has been obtained by Fiedler and Mallet–Paret in [20]. They proved that the Poincaré–Bendixson property holds for (1.2) on $T^1$, by using the properties of the zero number (see Theorem 3.1). The realization of any two-dimensional flow in a two-dimensional invariant manifold of the parabolic equation on the circle has been proved by Sandstede and Fiedler in [86]. Very recently, Czaja and Rocha have shown in [18] that the stable and unstable manifolds of two hyperbolic periodic orbits always intersect transversally and that there is no homoclinic connection for a periodic orbit. The other automatic transversality results and the proof of the genericity of the Morse–Smale property have been completed by the authors in [48] and [49].

- $d = 2$ and $\Omega = T^1$, radial symmetry and $T^1$-equivariance

When the vector field $g$ satisfies a radial symmetry, the dynamics of the two-dimensional flow generated by (1.1) becomes roughly one-dimensional. The closed orbits consist in 0, circles of equilibrium points and periodic orbits being circles described with a constant rotating speed. The dynamics are so constrained that the closed orbits being given, it is possible to describe all the heteroclinic connections. Notice that no homoclinic connection is possible. We also underline that the Morse–Smale property is generic in the class of radially symmetric vector fields.

If the two-dimensional radial vector fields are too simple to attract much attention, the corresponding case for the parabolic equation (1.2) on $\Omega = T^1$ with homogeneous nonlinearity $f(x, u, \partial_x u) \equiv f(u, \partial_x u)$ has been extensively studied. Since Theorem 3.1 holds for (1.2) with any one-dimensional domain $\Omega$, it is natural to expect results for (1.2) on $\Omega = T^1$ similar to the ones obtained for (1.2) on $\Omega = (0,1)$. In particular, one may wonder if it is possible to describe the global dynamics of (1.2) knowing the equilibria and the periodic orbits only. However, this property is still open for general nonlinearities $f(x, u, \partial_x u)$ in the case $\Omega = T^1$. Moreover, if one believes in the correspondence stated in this paper, one can claim that it is in fact false for a general nonlinearity $f(x, u, \partial_x u)$. Therefore, it was natural to first study the simpler case of homogeneous nonlinearities $f \equiv f(u, \partial_x u)$. Indeed, the dynamics in this case are much simpler, in particular the closed orbits are either homogeneous equilibrium points $e(x) \equiv e \in \mathbb{R}$, or circles of nonhomogeneous equilibrium points, or periodic orbits consisting in rotating waves $u(x, t) = u(x - ct)$ (notice the correspondence with the closed orbits of a radially
symmetric two-dimensional flow). This property is a consequence of the zero number property of Theorem 3.1 and has been proved in [4] by Angenent and Fiedler. The works of Matano and Nakamura [55] and of Fiedler, Rocha and Wolfrum [24] show that the unstable and stable manifolds of the equilibria and the periodic orbits always intersect transversally and that no homoclinic orbit can occur. Moreover, in [24], the authors give an algorithm for determining the global dynamics of the parabolic equation (1.2) on $\Omega = \mathbb{T}^1$ with homogeneous nonlinearity $f \equiv f(u, \partial_x u)$. This algorithm uses the knowledge of the equilibria and the periodic orbits only. In [84], Rocha also characterized all the dynamics, which may occur. Due to the automatic transverse intersection of the stable and unstable manifolds and due to the possibility of transforming any circle of equilibrium points into a rotating periodic orbit (see [24]), one can show that the Morse–Smale property holds for the parabolic equation on $\mathbb{T}^1$ for a generic homogeneous nonlinearity $f(u, \partial_x u)$ (see [48]). Finally, the realization of any radially symmetric two-dimensional flow in the dynamics of (1.2) on $\mathbb{T}^1$ for some $f \equiv f(u, \partial_x u)$ and the fact that the dimension of the attractor is equal to the largest dimension of the unstable manifolds are shown in [36].

- $d \geq 3$ and $\text{dim}(\Omega) \geq 2$

The genericity of the Kupka–Smale property for vector fields in $\mathbb{R}^d$, $d \geq 3$, has been proved independently by Kupka in [51] and by Smale in [88]. Their proofs have been simplified by Peixoto in [65] (see [1] and [62]). The strong difference with the lower dimensional vector fields is that, when $d \geq 3$, (1.1) may admit transversal homoclinic orbits consisting in the transversal intersection of the stable and unstable manifolds of a hyperbolic periodic orbit. The existence of such an intersection is stable under small perturbations and yields a Smale horseshoe containing an infinite number of periodic orbits and chaotic dynamics equivalent to the dynamics of the shift operator, see [89]. Therefore, the Morse–Smale property cannot be dense in vector fields on $\mathbb{R}^d$ with $d \geq 3$. Even worse, the set of vector fields, whose dynamics are structurally stable under small perturbations, is not dense (notice that this set contains the vector fields satisfying the Morse–Smale property). Indeed, as shown in [33], there exists an open set $\mathcal{U}$ of vector fields of $\mathbb{R}^3$ and a foliation of $\mathcal{U}$ by 2-codimensional leaves $(\mathcal{U}_\lambda)_{\lambda \in \mathbb{R}^2}$ such that each $g \in \mathcal{U}$ admits a Lorenz attractor $A_g$ and such that the dynamics of two attractors $A_g$ and $A_\tilde{g}$ are qualitatively equivalent if and only if $g$ and $\tilde{g}$ belong to the same leaf $\mathcal{U}_\lambda$. The possible presence of other chaotic dynamics such as Anosov systems or wild dynamics is also noteworthy, see [5, 56] and [9]. For the interested reader, we refer to [81] or [90].

The genericity of the Kupka–Smale property for the parabolic equation (1.2) on any domain $\Omega$ is proved by Brunovský and both authors in [13]. There exist several results concerning the embedding of the finite-dimensional flows into the parabolic equations. Poláčik has shown in [69] that any ordinary differential equation on $\mathbb{R}^d$ can be embedded into the flow of (1.2) for some $f$ and for some domain $\Omega \subset \mathbb{R}^d$. The constraint that the dimension of $\Omega$ is equal to the dimension of the imbedded flow is removed in [70], however the result concerns a dense set of flows only. A similar result has been obtained by Dancer and Poláčik in [19] for homogeneous
nonlinearities \( f(u, \nabla u) \) (see also [74]). These realization results imply the possible existence of persistent chaotic dynamics in the flow of the parabolic equation (1.2) as soon as \( \Omega \) has a dimension larger than one: transversal homoclinic orbits, Anosov flows on invariant manifolds of any dimension, Lorenz attractors etc.

**• Gradient case**

When \( g \) is a gradient vector field \( \nabla G \) with \( G \in C^2(\mathbb{R}^d, \mathbb{R}) \), then \(-G\) is a strict Lyapunov function and (1.1) is a gradient system. In this case, the Kupka–Smale property is equivalent to the Morse–Smale property. The genericity of the Morse–Smale property for gradient vector fields has been obtained by Smale in [87].

In the case where the nonlinearity \( f \in C^r(\Omega \times \mathbb{R}, \mathbb{R}) \) (that is, \( f \equiv f(x, u) \) does not depend on \( \nabla u \)), the parabolic equation (1.2) admits a strict Lyapunov function given by \( E(u) = \int_\Omega \left( \frac{1}{2} |\nabla u(x)|^2 - F(x, u(x)) \right) dx \), where \( F(x, u) = \int_0^u f(x, s) ds \) is a primitive of \( f \), and hence generates a gradient system. Brunovsky and Poláčik have shown in [14] that the Morse–Smale property holds for the parabolic equation, generically with respect to \( f(x, u) \). It is noteworthy that the Morse–Smale property is no longer generic if one restricts the nonlinearities to the class of homogeneous functions \( f \equiv f(u) \) (see [72]). Poláčik has shown in [71] that any generic gradient vector field of \( \mathbb{R}^d \) can be realized in the flow of the parabolic equation (1.2) on a bounded domain of \( \mathbb{R}^2 \) with an appropriate nonlinearity \( f(x, u) \). The paper [71] also contains the realization of particular dynamics such as non-transversal intersections of stable and unstable manifolds.

**• Caveat: general ODEs or cooperative systems?**

In Table 1, we have given the striking correspondence between the flow generated by Eq. (1.1) and the semiflow generated by the parabolic equation (1.2). In addition, we have pointed out that some classes of cooperative systems are also involved in this correspondence. In fact, the reader should be aware that the dynamics of (1.2) is much closer to the ones of a cooperative system than to the ones of the general vector field (1.1). Indeed, the semiflow \( S_f(t) \) generated by the parabolic equation (1.2) belongs to the class of strongly monotone semiflows, which means that this semiflow has more constraints than the flow \( T_g(t) \) generated by a general vector field \( g \) (see Sec. 4). That is why, it could be more relevant to write Table 1 in terms of cooperative systems only (for example, by replacing the case of the general ODE with \( d \geq 3 \) by the case of a cooperative system of ODEs in dimension \( d \geq 4 \)). However, we have chosen to mainly write Table 1 in terms of general ODEs for several reasons:

- as far as the properties stated in Table 1 are concerned, there is no difference between the dynamics of a general ODE and the ones of a parabolic PDE,
- the dynamics of general ODEs are common knowledge, whereas speaking in terms of cooperative systems may not give a good insight of the dynamics of (1.2),
- not all the properties stated in Table 1 are known for the class of cooperative systems (for example the genericity of Kupka–Smale property is not yet known for \( d \geq 4 \)).
3. Zero Number and Unique Continuation Properties for the Scalar Parabolic Equation

The results presented in Table 1 and in Sec. 2 strongly rely on properties specific to the parabolic equations. The purpose of this section is to give a first insight of these particular properties and of their use, to the reader.

Dynamical systems generated by vectors fields are flows on $\mathbb{R}^d$, whereas the phase-space of the parabolic equation is an infinite-dimensional space $X^\alpha$. It is important to be aware of the fact that the parabolic equations generate only a small part of all possible dynamical systems on the Banach space $X^\alpha$. On one hand, this implies less freedom in perturbing the dynamics and hence in obtaining density results. In particular, whereas one can easily construct perturbations of a vector field $g$ which are localized in the phase space $\mathbb{R}^d$, the perturbations of the nonlinearity $f$ act in a nonlocal way on $X^\alpha$ (many different functions $u$ can have the same values of $u$ and $\nabla u$ at a given point $x$). Therefore, it is important to obtain unique continuation results in order to find values $(x, u, \nabla u)$, which are reached only once by a given periodic, heteroclinic or homoclinic orbit. On the other hand, the small class of dynamics generated by the parabolic equations admits special properties. These properties may in particular yield the constraints, which make the dynamics similar to the ones of low-dimensional vector fields.

The scalar parabolic equation in space dimension one ($\Omega = (0, 1)$ or $T^1$) satisfies a very strong property: the number of zeros of the solutions of the linearized equation is nonincreasing in time. This property is often called Sturm property since it goes back to Sturm [95] in 1836. There are different versions of this result, which have been proved by Nickel [58], Matano [53, 54], Angenent and Fiedler [3, 4] and Chen [16] (see also [30] for a survey). By similar techniques, a geometrical result on braids formed by solutions of the one-dimensional parabolic equation is obtained in [32].

**Theorem 3.1.** Let $\Omega = (0, 1)$ with Neumann boundary conditions or $\Omega = T^1$. Let $T > 0$, $a \in W^{1,\infty}(\Omega \times [0, T], \mathbb{R})$ and $b \in L^\infty(\Omega \times [0, T], \mathbb{R})$. Let $v: \Omega \times (0, T) \to \mathbb{R}$ be a bounded nontrivial classical solution of

$$
\partial_t v = \partial_{xx}^2 v + a(x, t)\partial_x v + b(x, t)v, \quad (x, t) \in \Omega \times (0, T).
$$

Then, for any $t \in (0, T)$, the number of zeros of the function $x \mapsto v(x, t)$ is finite and non-increasing in time. Moreover, it strictly decreases at $t = t_0$ if and only if $x \mapsto v(x, t_0)$ has a multiple zero.

Theorem 3.1 is the fundamental ingredient of almost all the results given in Table 1 in the cases $\Omega = (0, 1)$ and $\Omega = T^1$. It can be used either as a strong comparison principle or as a strong unique continuation property, as shown in the following examples of applications. General surveys can be found in [25, 35] and [36].

In the first application presented here, Theorem 3.1 is used as a strong maximum principle. In some sense, it yields an order on the phase space which is preserved...
by the flow. This illustrates how Theorem 3.1 may imply constraints similar to the
terms of low-dimensional vector fields. The following result was first proved in [97]
and the proof given here comes from [53] (see also [25]).

**Proposition 3.2.** Let \( \Omega = (0,1) \), let \( u_0 \in X^\infty \) and let \( u(x,t) \) be the corresponding
solution of the parabolic equation (1.2) with homogeneous Neumann boundary
conditions. The \( \omega \)-limit set of \( u_0 \) consists of a single equilibrium point.

**Proof.** We first notice that \( v(x,t) = \partial_t u(x,t) \) satisfies the equation
\[
\partial_t v(x,t) = \partial_{xx}^2 v(x,t) + f'(x,u(x,t) \partial_x u(x,t)) v(x,t)
+ \partial'_v (x,u(x,t),\partial_x u(x,t)) \partial_x v(x,t).
\]
Due to the Neumann boundary conditions, we have \( \partial_x u(0,t) = \partial_x^2 u(0,t) =
\partial_x v(0,t) = 0 \) for all \( t > 0 \). In particular, as soon as \( v(0,t) = 0, v(t) \) has a
double zero at \( x = 0 \). Due to Theorem 3.1, either \( v \) is a trivial solution, that is \( v \equiv 0 \)
for all \( t \), and \( u \) is an equilibrium point, or \( v(0,t) \) vanishes at most a finite number
of times since \( v(t) \) can have a multiple zero only a finite number of times. Assume
that \( u \) is not an equilibrium, then \( u(0,t) \) must be monotone for large times and thus
converges to \( a \in \mathbb{R} \). Any trajectory \( w \) in the \( \omega \)-limit set of \( u_0 \) must hence satisfy
\( w(0,t) = a \) for all \( t \). Therefore, \( \partial_t w(0,t) = 0 \) for all \( t \) and \( \partial_t w(0,t) \) has a multiple
zero at \( x = 0 \) for all times. Using Theorem 3.1, we deduce as above that \( w \) is an
equilibrium point of (1.2). But there exists at most one equilibrium \( w \) satisfying
\( w(0) = a \) and the Neumann boundary condition \( \partial_x w(0) = 0 \). Therefore, the \( \omega \)-limit
set of \( u_0 \) is a single equilibrium point \( w \).

The second application comes from [48]. It shows how Theorem 3.1 can be
used as a unique continuation property. This kind of property roughly says that,
if two solutions coincide too much near a point \( (x_0,t_0) \), then they must be equal
everywhere. The motivation beyond this example of application is the following.
We consider a time-periodic solution of (1.2) on \( \Omega = \mathbb{T}^1 \). The problem is to find a
perturbation of the nonlinearity \( f \), which makes this periodic orbit hyperbolic. As
enhanced above, such a perturbation is nonlocal in the phase space of (1.2). To be
able to perform perturbation arguments, it is important to show that one can find
a perturbation of \( f \) which acts only locally on the periodic orbit. To this end, one
proves the following result.

**Proposition 3.3.** Let \( p(x,t) \) be a periodic orbit of (1.2) on \( \Omega = \mathbb{T}^1 \). Let \( T > 0 \) be
its minimal period. Then, the map
\[
(x,t) \in \mathbb{T}^1 \times [0,T) \mapsto (x,p(x,t),\partial_x p(x,t))
\]
is one-to-one.

**Proof.** Assume that this map is not injective. Then there exist \( x_0, t_0 \in [0,T) \) and
\( t_1 \in [0,T) \), \( t_0 \neq t_1 \) such that
\[
p(x_0,t_0) = p(x_0,t_1) \quad \text{and} \quad \partial_x p(x_0,t_0) = \partial_x p(x_0,t_1).
\]
The function \( v(x, t) = p(x, t + t_1 - t_0) - p(x, t) \) is a solution of the equation
\[
\partial_t v(x, t) = \partial^2_{xx} v(x, t) + a(x, t)v(x, t) + b(x, t)\partial_x v(x, t),
\]
where \( a(x, t) = \int_0^1 f_s''(x, p(x(t') + s(p(x(t') + t_1 - t_0) - p(x, t')))ds \)
and \( b(x, t) = \int_0^1 f_s''(x, p(x(t') + s(p(x(t') + t_1 - t_0) - p(x, t')))ds \).
Moreover, the function \( v(x, t) \) satisfies \( v(x_0, t_0) = 0 \) and \( \partial_x v(x_0, t_0) = 0 \) and does not vanish everywhere since \( |t_1 - t_0| < T \). Due to Theorem 3.1, the number of zeros of \( v(t) \) drops strictly at \( t = t_0 \) and never increases. However, \( v(t) \) is a periodic function of period \( T \), and thus, its number of zeros is periodic. This leads to a contradiction and proves the proposition.

In a domain \( \Omega \) of dimension \( d' \geq 2 \), there is no known counterpart for Theorem 3.1 as shown in [29]. In particular, Proposition 3.3 does no longer hold. However, to be able to construct relevant perturbations of periodic orbits, one needs a result similar to Proposition 3.3, even if weaker. The following result can be found in [13]. Its proof is based on a generalization of the arguments of [38] and on unique continuations properties of the parabolic equations.

**Theorem 3.4.** Let \( p(x, t) \) be a periodic orbit of (1.2) with minimal period \( T > 0 \). There exists a generic set of points \( (x_0, t_0) \in \Omega \times [0, T) \) such that if \( t \in [0, T) \) satisfies \( p(x_0, t) = p(x_0, t_0) \) and \( \nabla p(x_0, t) = \nabla p(x_0, t_0) \), then \( t = t_0 \).

## 4. Cooperative Systems of ODEs

We consider a system of differential equations
\[
\dot{y}(t) = g(y(t)), \quad y(0) = y_0 \in \mathbb{R}^N,
\]
where \( g = (g_i)_{i=1,\ldots,N} \) is a \( \mathcal{C}^1 \) vector field.

Due to the analogy with biological models, the following definitions are natural. We say that (4.1) is a cooperative (respectively competitive) system if for any \( y \in \mathbb{R}^N \) and \( i \neq j \), \( \partial_{y_i}g_j(y) \) is non-negative (respectively non-positive) and the matrix \( (\partial_{y_i}g_j(y)) \) is irreducible, i.e. it is not a block diagonal matrix (the simpler assumption that all the coefficients \( \partial_{y_i}g_j(y) \) are positive is sometimes made instead of the irreducibility).

We say that (4.1) is a tridiagonal system if \( \partial_{y_i}g_j = 0 \) for \( |i - j| \geq 2 \) and a cyclic tridiagonal system if the indices \( i \) and \( j \) are considered modulo \( N \), i.e. if, in addition, we allow \( \partial_{y_N}g_1 \) and \( \partial_{y_1}g_N \) to be nonzero. For the reader interested in cooperative systems, we refer to [94].

In this section, we only consider cooperative systems. However, notice that, by changing \( t \) into \(-t\) or \( y_i \) into \(-y_i \), we obtain similar results for competitive systems and for systems with different sign conditions.

The dynamics of cooperative systems may be as complicated as the dynamics of general vector fields. Indeed, Smale has shown in [91] that any vector field in \( \mathbb{R}^{N-1} \) can be realized in an invariant manifold of a cooperative system in \( \mathbb{R}^N \). Notice
that this realization result implies that any one-dimensional vector field can be imbedded in a tridiagonal cooperative system and any two-dimensional vector field can be imbedded in a cyclic tridiagonal cooperative system. This explains why we present the tridiagonal cooperative systems in Table 1 as generalization of one- and two-dimensional vector fields.

However, the dynamics of a cooperative system \((4.1)\) is really different from the ones of the general ODE \((1.1)\) since a cooperative system generates a strongly monotone flow, that is, a flow which preserves a partial order. It is noteworthy that the semiflow \(S_f(t)\) generated by the parabolic equation \((1.2)\) also belongs to the class of strongly monotone semiflows (it preserves the order of \(X^\alpha\) induced by the classical order of \(C^0(\Omega)\)). Therefore, the semiflow of \((1.2)\) is much closer to the one of the cooperative system \((4.1)\), both admitting more constraints than the flow \(T_g(t)\) generated by a general vector field \(g\). In [42] and [45] for example, Hirsch has shown that almost all bounded trajectories of a strongly monotone semiflow are quasiconvergent, that is, their \(\omega\)-limit sets consist only of equilibria. More precisely, all initial data, which have bounded nonquasiconvergent trajectories, form a meager subset (that is, the complement of a generic subset) of the phase space. Later, in [68], Poláčik has proved that the set of all initial data \(u_0 \in X^\alpha\), which have bounded nonconvergent trajectories in the semiflow of the parabolic equation \((1.2)\), is meager in \(X^\alpha\).

Moreover, since the works of Hirsch and Smillie, it is known that the dynamics of cooperative systems, which are in addition tridiagonal, are very constrained in any dimension \(N\). Indeed, in [43, 44] and [92], strong properties of the limit sets of cooperative systems are proved. In particular, any three-dimensional cooperative system satisfies the Poincaré–Bendixson property and the trajectory of any tridiagonal cooperative system converges to a single equilibrium point. Inspired by the articles of Henry and Angenent about the parabolic equation on \((0,1)\), Fusco and Oliva (see [26]) showed a theorem similar to Theorem 3.1 (see [93] for a more general statement).

**Theorem 4.1.** Let \(N\) be the set of vector \(y \in \mathbb{R}^N\) such that, for all \(i = 1, \ldots, N\), either \(y_i \neq 0\) or \(y_i = 0\) and \(y_{i-1} y_{i+1} < 0\) (where \(y_0 = y_{N+1} = 0\)). For every \(y \in N\), we set \(N(y)\) to be the number of sign changes for \(y_i\), when \(i\) goes from 1 to \(N\). Let \(y(t) \neq 0\) be a solution of

\[
\dot{y}(t) = A(t)y(t),
\]

where \(A \in C^0(\mathbb{R}, \mathcal{M}_N(\mathbb{R}))\) satisfies \(A_{ij}(t) > 0\) for all \(t \in \mathbb{R}\) and all \(i \neq j\).

Then, the times \(t\) where \(y(t) \notin N\) are isolated and, if \(y(t_0) \notin N\), then, for every \(\varepsilon > 0\) small enough, \(N(y(t + \varepsilon)) < N(y(t - \varepsilon))\).

In other words, the number of sign changes of the solutions of the linear equation \((4.2)\) is non-increasing in time and strictly drops at \(t_0\) if and only if \(y(t_0)\) has in some sense a multiple zero. The parallel with Theorem 3.1 is of course striking. Using Theorem 4.1, Fusco and Oliva have shown that the stable and unstable manifolds of
Similitude Between the Dynamics of ODEs and of Parabolic Equations

equilibrium points of a tridiagonal cooperative system always intersect transversally. As a consequence, the Morse–Smale property is generic in the class of tridiagonal cooperative systems.

Theorem 4.1 also holds for cyclic tridiagonal cooperative systems, see [27] and [93]. Using this fundamental property, Fusco and Oliva have shown in [27] that the stable and unstable manifolds of periodic orbits of cyclic tridiagonal cooperative systems always intersect transversally. In addition, Mallet-Paret and Smith have shown in [52] that cyclic tridiagonal cooperative systems satisfy the Poincaré–Bendixson property. Notice that, following [48] and [49], one should be able to prove the genericity of the Morse–Smale property for cyclic tridiagonal cooperative systems. This has been proved very recently by Percie du Sert (see [66]).

Considering all these results, it is not surprising that there exists a parallel between tridiagonal cooperative systems and the parabolic equation on \((0, 1)\).

Indeed, consider a solution \(v\) of the linear one-dimensional parabolic equation

\[
\dot{v}(x, t) = \partial^2_{xx}v(x, t) + a(x, t)\partial_x v(x, t) + b(x, t)v(x, t), \quad (x, t) \in \mathbb{R} \times \mathbb{R}_+.
\]  

(4.3)

We discretize the segment \((0, 1)\) by a sequence of points \(x_k = (k - 1)/(N - 1)\) with \(k = 1, \ldots, N\). The natural approximation of \(v\) is given by \(y_k \approx v(x_k)\) solution of

\[
\dot{y}_k(t) = \frac{y_{k+1}(t) - 2y_k(t) + y_{k-1}(t)}{h^2} + a_k(t)\frac{y_{k+1} - y_k}{h} + b_k(t)y_k(t),
\]

(4.4)

where \(a_k(t) = a(x_k, t)\), \(b_k(t) = b(x_k, t)\) and \(h = 1/(N - 1)\). If \(h\) is small enough, (4.4) is a tridiagonal cooperative system. The relation between Theorems 3.1 and 4.1 is obvious in this framework.

5. Beyond Kupka–Smale and Other Open Problems

One of the main goals of the study of dynamical systems is to understand the behavior of a generic dynamical system. The most recent results concerning the parabolic equations are related to the genericity of Kupka–Smale property. However, such a property cannot give a good insight of the complex and chaotic dynamics that may be generated by homoclinic connections. For this reason, the study of finite-dimensional flows has been pursued further the Kupka–Smale property and is still in progress. The corresponding results should serve as a guideline for the study of the flow generated by the parabolic equation (1.2).

As for vector fields, going beyond the Kupka–Smale genericity property for scalar parabolic equations will be an important and difficult problem. For vector fields, one of the main steps for this purpose is Pugh’s closing lemma: if \(p\) is a non-wandering point of the dynamical system \(T_g(t)\) generated by (1.1), then there exists a \(C^1\)-perturbation \(\tilde{g}\) of \(g\) such that \(p\) is a periodic point of \(T_{\tilde{g}}(t)\) (the case of a \(C^r\)-perturbation with \(r \geq 2\) is still open). The proof of Pugh in [75] concerns discrete dynamical systems. It has been adapted to the case of flows by Pugh and Robinson in [77] (see also [80] for an introduction to the proof). A direct consequence of Pugh closing lemma is the general density theorem: for a generic finite-dimensional
flow, the non-wandering points are the closure of the periodic points (see [76] and
[81]). Other connecting lemmas have been proved by Hayashi [39] and Bonatti
and Crovisier [8]. They enable a better understanding of generic dynamics. For
example, the class of finite-dimensional dynamical systems which either satisfy
the Morse–Smale property or admit a transversal homoclinic connection is generic
(see [78, 10] and [17] for discrete dynamical systems in dimensions \(d = 2\), \(d = 3\) and
\(d \geq 4\) respectively, and see [6] for three-dimensional flows). Obtaining similar
results for the flow of the parabolic equation should be a very interesting and
difficult challenge.

Other interesting open problems concern the realization of finite-dimensional
dynamics in the semiflow of parabolic equations. Indeed, we only know that one
can realize the dynamics of a dense set of general ODEs in the flow of a parabolic
equation (1.2) on a two-dimensional domain. One may wonder if it is possible to
realize the dynamics of all ODEs. Since the parallel between parabolic equations
and cooperative systems is stronger, the following strong realization conjecture may
be more plausible: any flow of a cooperative system of ODEs can be realized in an
invariant manifold of the flow of a parabolic equation (1.2) on a two-dimensional
domain.

Finally, the genericity of the Morse- and Kupka–Smale properties is also an inter-
esting problem for other classes of partial differential equations. The genericity of
the Morse–Smale property is known for the wave equations \(\ddot{u} + \gamma \dot{u} = \Delta u + f(x, u)\)
with constant damping \(\gamma > 0\) (see [15]) and with variable damping \(\gamma(x) \geq 0\)
in space dimension one (see [47]). We recall that, in both cases, the associated
dynamical system is gradient. Nothing is known for other classes of PDEs, in partic-
ular for the equations of fluids dynamics and for systems of parabolic equations
\(\dot{U} = \Delta U + f(x, U)\), with \(U(x, t) \in \mathbb{R}^N\). In all these cases, the main problem consists
in understanding how the perturbations act on the phase plane of the PDE. Either
one proves unique continuation results similar to Theorem 3.4 in order to be able
to use local perturbations of the flow (as in [48, 49] and [13]), or one uses particular
nonlocal perturbations in a very careful way (as in [14, 15] and [47]).

6. Glossary

In this section, \(S(t)\) denotes a general continuous dynamical system on a Banach
space \(X\). An orbit of \(S(t)\) is denoted by \(x(t) = S(t)x_0\) with \(t \in I\), where \(I = [0, +\infty)\),
\(I = (-\infty, 0]\) or \(I = (-\infty, +\infty)\) in the case of a positive, negative or global trajectory
respectively.

Compact global attractor: If it exists, the compact global attractor \(\mathcal{A}\) of \(S(t)\)
is a compact invariant set which attracts all the bounded sets of \(X\). Notice that \(\mathcal{A}\)
is then the set of all the bounded global trajectories. See [34].

\(\alpha\)- and \(\omega\)-limit sets: Let \(x_0 \in X\). The \(\alpha\)-limit set \(\alpha(x_0)\) and the \(\omega\)-limit set \(\omega(x_0)\)
of \(x_0\) are the sets of accumulation points of the negative and positive orbits coming
from \( x_0 \) respectively. More precisely,

\[
\alpha(x_0) = \left\{ x \in X/ \exists (t_n)_{n \in \mathbb{N}}, \ t_n \xrightarrow{n \to \infty} -\infty \text{ and a negative trajectory } x(t) \right\},
\]

\[
\omega(x_0) = \left\{ x \in X/ \exists (t_n)_{n \in \mathbb{N}}, \ t_n \xrightarrow{n \to \infty} +\infty \text{ such that } S(t_n)x_0 \xrightarrow{n \to \infty} x \right\}.
\]

The limit sets \( \alpha(x_0) \) and \( \omega(x_0) \) are non-empty connected compact sets.

**Homoclinic or heteroclinic orbit:** Let \( x(t) = S(t)x_0 \) be a global trajectory of \( S(t) \). Assume that the \( \alpha \)- and \( \omega \)-limit sets of \( x_0 \) exactly consists in one orbit, denoted \( x_-(t) \) and \( x_+(t) \) respectively, this orbit being either an equilibrium point or a periodic orbit. The trajectory \( x(t) \) is said to be a homoclinic orbit if \( x_-(t) = x_+(t) \) and a heteroclinic orbit if \( x_-(t) \neq x_+(t) \).

**Backward uniqueness property:** \( S(t) \) satisfies the backward uniqueness property if for any time \( t_0 > 0 \) and any trajectories \( x_1(t) \) and \( x_2(t) \), \( x_1(t_0) = x_2(t_0) \) implies \( x_1(t) = x_2(t) \) for all \( t \in [0,t_0] \). Notice that this does not mean that \( S(t) \) admits negative trajectories.

**Hyperbolic equilibrium points or periodic orbits:** An equilibrium point \( e \) of \( S(t) \) is hyperbolic if the linearized operator \( x \mapsto D_eS(1)x \) has no spectrum on the unit circle. Let \( p(t) \) be a periodic solution of \( S(t) \) with minimal period \( T \). For each \( x \in X \), we denote \( t \mapsto \Pi(t,0)x \) the corresponding trajectory of the linearization of \( S(t) \) along the periodic solution \( p(t) \). Then, \( p(t) \) is said to be hyperbolic if the linear map \( x \mapsto \Pi(T,0)x \) has no spectrum on the unit circle except the eigenvalue 1 which is simple. Remark that then, for any integer \( k \neq 0 \), the linear map \( x \mapsto \Pi(kT,0)x \) has no spectrum on the unit circle except the eigenvalue 1 (which is simple).

**Stable and unstable manifolds:** Let \( e \) be a hyperbolic equilibrium point of \( S(t) \). There exists a neighborhood \( \mathcal{N} \) of \( e \) such that the set

\[
W^u_{\text{loc}}(e) = \left\{ x_0 \in X, \exists \text{ a negative trajectory } x(t) \text{ with } x(0) = x_0 \right\}
\]

is a submanifold of \( X \), in which all negative trajectories converge to \( e \) when \( t \) goes to \(-\infty\). The manifold \( W^u_{\text{loc}}(e) \) is called the local unstable manifold of \( e \). Pushing \( W^u_{\text{loc}}(e) \) by the flow \( S(t) \), one can define the (global) unstable set \( W^u(e) = \cup_{t \geq 0} S(t)W^u_{\text{loc}}(e) \), which consists in all the negative trajectories converging to \( e \) when \( t \) goes to \(-\infty\). This unstable set \( W^u(e) \) is an immersed submanifold under suitable properties. For instance, backward uniqueness properties are needed to extend the manifold structure.
In the same way, one defines the local stable manifold

\[ W^s_{\text{loc}}(e) = \left\{ x_0 \in X, \forall t \geq 0, S(t)x_0 \in \mathcal{N} \right\} = \left\{ x_0 \in X, \forall t \geq 0, S(t)x_0 \in \mathcal{N} \text{ and } S(t)x_0 \xrightarrow{t \to +\infty} e \right\}. \]

General partial differential equations (and parabolic equations in particular) do not admit negative trajectories. Therefore, it is less easy to extend the local stable manifold to a global stable manifold. However, one can define the stable set \( W^s(e) \) of \( e \) as follows:

\[ W^s(e) = \left\{ x_0 \in X, S(t)x_0 \xrightarrow{t \to +\infty} e \right\}. \]

Under suitable additional properties (which are satisfied by the parabolic equation (1.2)), one can show that \( W^s(e) \) is also an immersed submanifold. For instance, backward uniqueness properties of the adjoint dynamical system \( S^*(t) \) on \( X^* \) and finite-codimensionality of \( W^s_{\text{loc}}(e) \) are needed (see [41] for more details).

If \( p(t) \) is a hyperbolic periodic orbit, one defines its unstable and local stable manifolds in the same way. See for example [62] for more details.

**Non-wandering set:** A point \( x_0 \in X \) is non-wandering if for any neighborhood \( \mathcal{N} \ni x_0 \) and any time \( t_0 > 0 \), there exists \( t \geq t_0 \) such that \( S(t)\mathcal{N} \cap \mathcal{N} \neq \emptyset \).

**The Kupka–Smale and Morse–Smale properties:** \( S(t) \) satisfies the Kupka–Smale property if all its equilibrium points and periodic orbits are hyperbolic and if their stable and unstable manifolds intersect transversely. It satisfies the Morse–Smale property if in addition its non-wandering set consists only in a finite number of equilibrium points and periodic orbits. We refer to [62] for more precisions on these notions.

**Gradient dynamical systems:** \( S(t) \) is gradient if it admits a Lyapunov functional, that is a function \( \Phi \in C^0(X, \mathbb{R}) \) such that, for all \( x_0 \in X \), \( t \mapsto \Phi(S(t)x_0) \) is non-increasing and is constant if and only if \( x_0 \) is an equilibrium point. We recall that a gradient dynamical system does not admit periodic or homoclinic orbits.

**Cooperative system of ODEs:** See Sec. 4.

**Generic set and Baire space:** A generic subset of a topological space \( Y \) is a set which contains a countable intersection of dense open subsets of \( Y \). A property is generic in \( Y \) if it is satisfied for a generic set of \( Y \). The space \( Y \) is called a Baire space if any generic set is dense in \( Y \). In particular, a complete metric space is a Baire space.

**Whitney topology:** Let \( k \geq 0 \) and let \( M \) be a Banach manifold. The Whitney topology on \( C^k(M, \mathbb{R}) \) is the topology generated by the neighborhoods

\[ \{ g \in C^k(M, \mathbb{R}), |D^i f(x) - D^i g(x)| \leq \delta(x), \forall i \in \{0, 1, \ldots, k\}, \forall x \in M \}, \]
where \( f \) is any function in \( C^k(M, \mathbb{R}) \) and \( \delta \) is any positive function in \( C^k(M, (0, +\infty)) \). Notice that \( C^k(M, \mathbb{R}) \) endowed with the Whitney topology is a Baire space even if it is not a metric space when \( M \) is not compact. We refer for instance to [31].

**The fractional power space** \( X^\alpha \): Let \( A \) be a positive self-adjoint operator with compact inverse on \( L^2(\Omega) \). Let \( (\lambda_n) \) be the sequence of its eigenvalues, which are positive, and let \( (\varphi_n) \) be the corresponding sequence of eigenfunctions, which is an orthonormal basis of \( L^2(\Omega) \). For each \( \alpha \in \mathbb{R} \), we define the fractional power of \( A \) by 
\[
A^{\alpha}(\sum_n c_n \varphi_n) = \sum_n c_n \lambda_n^{\alpha} \varphi_n.
\]
In particular, \( A^0 = \text{Id} \) and \( A^1 = A \). The space \( X^\alpha \) is the domain of \( A^\alpha \) that is 
\[
X^\alpha = \left\{ \varphi \in L^2(\Omega), \varphi = \sum_n c_n \varphi_n \text{ such that } (c_n \lambda_n^{\alpha}) \in \ell^2(\mathbb{N}) \right\}.
\]
It is possible to define fractional powers of more general operators, called sectorial operators, see [41].

**The Sobolev space** \( W^{s,p}(\Omega) \): If \( s \) is a positive integer, \( W^{s,p}(\Omega) \) is the space of (classes of) functions \( f \in L^p(\Omega) \), which are \( s \) times differentiable in the sense of distributions and whose derivatives up to order \( s \) belong to \( L^p(\Omega) \). It is possible to extend this notion to positive numbers \( s \) which are not integers by using interpolation theory.

**Unique continuation properties:** Let us consider a partial differential equation on \( \Omega \) and let \( u(x, t) \) be any solution of it. A unique continuation property for this PDE is a result stating that if \( u(x, t) \) vanishes on a subset of \( \Omega \times \mathbb{R}_+ \) which is too large in some sense, then \( u(x, t) \) must vanish for all \( (x, t) \) in \( \Omega \times \mathbb{R}_+ \).
