

Gradient Young measures, varifolds, and a generalized Willmore functional

Simon Masnou* and Giacomo Nardi**

August 31, 2012

Abstract

Being Ω an open and bounded Lipschitz domain of \mathbb{R}^n , we consider the *generalized Willmore functional* defined on $L^1(\Omega)$ as

$$F(u) = \begin{cases} \int_{\Omega} |\nabla u| (\alpha + \beta |\operatorname{div} \frac{\nabla u}{|\nabla u|}|^p) dx & \text{if } u \in C^2(\Omega), \\ +\infty & \text{else,} \end{cases}$$

where $p > 1$, $\alpha > 0$, $\beta \geq 0$. We propose a new framework, that combines varifolds and Young measures, to study the relaxation of F in $BV(\Omega)$ with respect to the strong topology of L^1 .

1 Introduction

Let Ω be an open bounded Lipschitz domain of \mathbb{R}^n . We address in this paper the problem of identifying the relaxation (with respect to the strong topology of $L^1(\Omega)$) of the functional

$$F(\cdot, \Omega) : u \in BV(\Omega) \mapsto \begin{cases} \int_{\Omega} |\nabla u| \left(\alpha + \beta \left| \operatorname{div} \frac{\nabla u}{|\nabla u|} \right|^p \right) dx & \text{if } u \in C^2(\Omega) \\ +\infty & \text{otherwise} \end{cases}$$

with $p > 1$, $\alpha > 0$, $\beta \geq 0$ and the convention that the integrand is 0 wherever $|\nabla u| = 0$. Here, $BV(\Omega)$ denotes the space of functions of bounded variation in Ω , see [3]. Without loss of generality and to simplify the notations, we shall assume in the sequel that $\alpha = \beta = 1$.

This functional appears, under various forms, in the context of optimal design of shapes or digital surfaces in 3D [5], modeling and approximation of elastic membranes, or folding in multi-layered materials [10], image or surface processing [22, 23, 12, 5]. In particular, it has been introduced in [22, 23] as a variational model in the context of digital image inpainting, i.e. the problem of recovering an image that is known only out of a given domain. It is also related to a model of amodal completion in a neurogeometric description of the visual cortex [13].

The functional F has a strong geometric meaning. Indeed, by the coarea formula [15, 3],

$$F(u, \Omega) = \int_{\mathbb{R}} \left[\int_{\partial\{u>t\} \cap \Omega} (1 + |\mathbf{H}_{\partial\{u>t\} \cap \Omega}|^p) d\mathcal{H}^{n-1} \right] dt \quad \forall u \in C^2(\Omega) \quad (1)$$

**Université Pierre et Marie Curie Paris 6, CNRS UMR 7598, Laboratoire Jacques-Louis Lions, F-75005, Paris, France. Email: nardi@ann.jussieu.fr

where, for a.e. t , $\mathbf{H}_{\partial\{u>t\}\cap\Omega}(x) = -(\operatorname{div} \frac{\nabla u}{|\nabla u|}) \frac{\nabla u}{|\nabla u|}(x)$ is the mean curvature vector at a point $x \in \partial\{u>t\} \cap \Omega$, and \mathcal{H}^{n-1} is the $(n-1)$ -Hausdorff measure. We call F a *generalized Willmore functional* for it naturally relates to the celebrated Willmore energy of an immersed compact oriented surface $f : \Sigma \rightarrow \mathbb{R}^N$ without boundary, defined as

$$\mathcal{W}(f) = \int_{\Sigma} |\mathbf{H}|^2 dA$$

with dA the induced area metric on Σ .

Minimizing F (for instance under fat boundary constraints) raises immediate difficulties for a simple reason: the functional is not lower semicontinuous with respect to the strong convergence in L^1 , as can be seen immediately from the following classical example [7]:

Example 1.1 Being E and Ω the planar sets drawn on Figure 1, left, let $u = \mathbb{1}_E$. Obviously, $u \in \operatorname{BV}(\Omega)$ can be approximated in L^1 by a sequence $\{u_h\} \subset C_c^2(\Omega)$ of functions with isolevel lines as in Figure 1, right. It is easy to check that $\liminf_{h \rightarrow \infty} F(u_h) < \infty$ but, since $u \notin C^2(\Omega)$, we

Figure 1: Left: $u = \mathbb{1}_E$ with $\bar{F}(u, \Omega) < \infty$. Right: Isolevel lines of a smooth approximating function.

have $F(u, \Omega) = \infty$ so F is not lower semicontinuous.

The usual technique in calculus of variations to overcome this difficulty consists in relaxing F , i.e., introducing the functional

$$\bar{F}(u, \Omega) = \inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : u_h \xrightarrow{L^1(\Omega)} u \right\}.$$

As a relaxation, this functional has the interesting property of being lower semicontinuous in L^1 [25]. Together with the relative compactness of BV in L^1 , it guarantees that the infimum of F coincides with a minimum of \bar{F} , which somewhat solves the minimization problem. It remains however that not much can be said neither about the minimizers of \bar{F} nor, more generally, about $\bar{F}(u)$ for a general function u with bounded variation.

Partial results have been obtained in [4, 21] in the case where u is smooth. Combining the techniques used in these papers with the more recent [26], it can be proved that, in any space dimension n and for any $p \geq 1$, $F(u) = \bar{F}(u)$ when u is C^2 . What about more general functions?

Examining again the previous example, it is clear that $\bar{F}(u) < +\infty$ since (u_h) has uniformly bounded energy and converges to u . Besides, it is equivalent to study \bar{F} for the function $u = \mathbb{1}_E$ or to study the relaxation at E of the following functional that acts on measurable sets (in our example $n = 2$):

$$A \subset \mathbb{R}^n \mapsto W(A) = \begin{cases} \int_{\partial A} (1 + |\mathbf{H}_{\partial A}|^p) d\mathcal{H}^{n-1} & \text{if } \partial A \text{ is smooth} \\ +\infty & \text{otherwise} \end{cases}$$

The relaxed functional associated with W is

$$\overline{W}(A) = \inf\{\liminf_{h \rightarrow \infty} W(A_h), (\partial A_h) \text{ smooth}, |A_h \Delta A| \rightarrow 0\},$$

where $|\cdot|$ denotes the Lebesgue measure.

The properties of bounded sets $A \subset \mathbb{R}^2$ such that $\overline{W}(A) < +\infty$ and the explicit representation of $\overline{W}(A)$ have been carefully studied in [7, 8, 9]. Such sets have finite perimeter (by definition of the energy) and, by explicit representation, we mean that $\overline{W}(A)$ can be written in terms of the $W^{2,p}$ norms of a collection of curves that cover the essential boundary $\partial^* A$ of A . This can again be easily understood from Example 1.1 and Figures 1, 2: a "good" way to approximate E in measure consists in choosing a set E_h whose boundary Γ^h is represented in Figure 2. These sets have uniformly bounded energy and, as shown in [7], $\overline{W}(E)$ coincides with $W(\Gamma) = \int_{\Gamma} (1 + |\kappa_{\Gamma}|^p) d\mathcal{H}^1$ (with κ_{Γ} the curvature along Γ) where Γ is the limit curve represented in Figure 2, right, with its multiplicity.

Figure 2: Accumulation at the limit of the boundaries of sets that approximate in measure the set E of Figure 1.

Having in mind the expression (1) of F through the coarea formula, it is natural to expect that, at least in dimension 2, the relaxed energy $\overline{F}(u)$ of a function u of bounded variation can be written in terms of the energies $W(\Gamma_t)$ of systems of curves (Γ_t) that cover the essential boundaries $\partial^*\{u > t\}$. This is exactly what happens, as we proved in the companion paper [24], among other results, by generalizing techniques that were proposed in [23] for a more restrictive boundary value problem involving the same energy. The precise statements will be recalled in Section 2.

The techniques developed in [7, 8, 9, 23, 24] depend strongly on parameterizations of curves and can hardly be generalized to higher space dimensions. Indeed, in dimension strictly greater than 2, parameterizations of hypersurfaces are much harder to handle in our context especially since the energy of interest controls the mean curvature vector only. We will come back later on this issue, that was the main motivation for the new framework that we introduce in this paper and that involves two specific tools: Young measures, that play a fundamental role in many problems of the calculus of variations, and varifolds, that appear to be very useful to handle generalized surfaces and a weak notion of mean curvature.

Varifolds The basic idea behind rectifiable varifolds, that will be introduced with more details in Section 4, is that each rectifiable k -subset $M \subset \mathbb{R}^n$ can be endowed with a multiplicity function θ_M and associated with the measure $\theta_M \mathcal{H}^k \llcorner M$. The associated varifold is the Radon measure $V_M = \mathbf{v}(M, \theta_M) = \theta_M \mathcal{H}^k \llcorner M \otimes \delta_{T_M(x)}$ on the product space $G_k(\Omega) = \Omega \times G(n, k)$, with $G(n, k)$ the Grassmannian of k -subspaces in \mathbb{R}^n and $T_M(x)$ the tangent space to M at $x \in \Gamma$. Therefore, varifolds carry information both on spatial localization and tangential behavior. Varifolds have nice properties, among which the possibility to use a weak notion of mean curvature, the continuity of the mass, a compactness property, the lower

semicontinuity of some useful second-order energies, etc. They are actually much more adapted than parameterizations for handling sequences of k -surfaces in \mathbb{R}^n when there is a control on the mean curvature.

Denoting $\mu_V(\cdot) = V(\cdot \times G(n, k))$ the mass of a k -varifold V in \mathbb{R}^n , we show in the following table how notions that are naturally defined for smooth k -sets can be easily translated in terms of k -varifolds. Here, X denotes a smooth vector field with compact support.

	M closed, smooth k -set	V k -varifold
Mass	$\mathcal{H}^k(M)$	$\mu_V = V(\Omega \times G(n, k))$
First variation	$\int_M \operatorname{div}_M X d\mathcal{H}^k$	$\delta V(X) = \int_{G_k(\Omega)} \operatorname{div}_S X dV(x, S)$
Mean curvature vector	\mathbf{H}_M s.t $\int_M \operatorname{div}_M X d\mathcal{H}^k = - \int_M \mathbf{H}_M \cdot X d\mathcal{H}^k$	$\mathbf{H}_V = - \frac{\delta V}{\mu_V}$

In particular, this table shows the divergence theorem that relates (the integral of) the tangential divergence of a smooth vector field with (the integral of) the mean curvature vector. Recalling that, for a smooth function u , $-(\operatorname{div} \frac{\nabla u}{|\nabla u|}) \frac{\nabla u}{|\nabla u|}(x)$ is the mean curvature vector at $x \in \partial\{u > t\}$, and

$$\operatorname{div}_{\{y, u(x)=u(y)\}} X = \operatorname{div}_{\nabla u^\perp} X$$

we calculate

$$\begin{aligned} \int_\Omega |\nabla u| \operatorname{div}_{\nabla u^\perp} X dx &= \int_{-\infty}^{+\infty} \int_{\Omega \cap \{u=t\}} \operatorname{div}_{\nabla u^\perp} X dx dt = - \int_{-\infty}^{+\infty} \int_{\Omega \cap \{u=t\}} \mathbf{H}_{\{u=t\}} \cdot X dx dt \\ &= - \int_\Omega |\nabla u| \mathbf{H}_{\{y, u(y)=u(x)\}} \cdot X dx \end{aligned}$$

This looks exactly like the formula provided by the divergence theorem, except that the Hausdorff measure has been replaced by the measure $|\nabla u| dx$. This observation is the core of our approach in a less regular context: roughly speaking, given a function u of bounded variation, we will define a varifold associated with the mass represented by the total variation. Then the first variation of the mass can be computed (like above), and considering the measure provided by the Riesz representation theorem, its Radon-Nikodym derivative with respect to the mass finally yields the mean curvature.

The first delicate issue is to extend properly to BV the quantity $\int_\Omega |\nabla u| \operatorname{div}_{\nabla u^\perp} X dx$ that belongs to the general family of mappings $u \mapsto \int_\Omega f(x, \nabla u) dx$. Studying such mappings in BV is the purpose of [20], where suitable tools are defined based on the theory of Young measures.

Young measures They were introduced by L.C. Young [30, 31, 32] to describe limits of minimizing sequences for integrals of the type

$$\int f(x, u) dx \quad \text{or} \quad \int f(x, u, \nabla u) dx$$

Young measures are particularly useful when classical minimizers do not exist. They can handle complex situations with concentration, oscillation, or diffusion phenomena. They find many applications in calculus of variations, optimal control theory, optimal design, variational modeling of nonlocal interactions, etc. [29, 11, 27].

The typical situation where they arise is the following: Ω being bounded, take a sequence (v_h) that converges weakly to v in $L^\infty(\Omega, \mathbb{R}^n)$, and look at $f(x, v_h(x))$ with f continuous and nonlinear. Then a classical theorem due to L.C. Young states that there exists a family of probability measures $(\nu_x)_{x \in \Omega}$, called Young measure generated by the sequence (v_h) , such that

$$\int_{\mathbb{R}^n} z \, d\nu_x(z) = v(x) \quad \mathcal{L}^n - \text{a.e. } x$$

and, up to a subsequence,

$$\int_{\Omega} f(x, v_h) \, dx = \int_{\Omega} \int_{\mathbb{R}^n} f(x, z) \delta_{v_h}(z) \, dx \rightarrow \int_{\Omega} \int_{\mathbb{R}^n} f(x, z) \nu_x(z) \, dx.$$

In other words, the impossibility to use the continuity of f is overcome by introducing a measure that, in some sense, carries the information out of f .

A frequent situation in the calculus of variations concerns the case where v_h are gradients, i.e. $v_h = \nabla u_h$ and $v = \nabla u$ for some $u_h, u \in W^{1,p}(\Omega)$. As above, every sequence of gradients that weakly converges in L^p generates a Young measure, called gradient Young measure.

Then it is natural to ask which families of probability measures are generated by sequences of gradients or, in other words, can one characterize the set of gradient Young measures?

In [18, 19] the authors study the gradient Young measures generated by a sequence of gradients converging weakly in $L^p(\Omega, \mathbb{R}^m)$ ($p > 1$) and their characterization essentially depends on the condition

$$\int_{\Omega} \int_{\mathbb{R}^n} |z|^p \, d\nu_x(z) \, dx < \infty.$$

Their results are generalizable to $p = \infty$ and to the vectorial case (i.e. for \mathbb{R}^d -valued functions, with $d > 1$), see [27] for precise statements.

In the applications, if $p > 1$, the weak convergence follows from a uniform bound on the $W^{1,p}$ norm of the gradients, but in the case $p = 1$ the space $W^{1,1}$ is not reflexive so, to infer weak relative compactness, the sequence $\{\nabla u_h\}$ should be equi-integrable, which is hard to establish in the applications. As an alternative, the weak-* topology of $BV(\Omega)$ can be considered, and leads to an extension of the concept of Young measures.

In [14, 1, 20], a new formulation for Young measures is introduced to extend the classical theory to the framework of functions of bounded variation. A generalized gradient Young measure ν is defined as a triplet of measures $\nu = (\nu_x, \nu_x^\infty, \lambda_\nu)$ where $(\nu_x)_{x \in \mathbb{R}^n}$ is a family of probability measures on \mathbb{R}^n , λ_ν is a positive bounded Radon measure on $\bar{\Omega}$ and $(\nu_x^\infty)_{x \in \mathbb{R}^n}$ is a family of probability measures on \mathbb{S}^{n-1} , the unit sphere of \mathbb{R}^n . The Young measure representation is extended to

$$\langle \langle \nu, f \rangle \rangle := \int_{\Omega} \int_{\mathbb{R}^n} f(x, z) \, d\nu_x(z) \, dx + \int_{\bar{\Omega}} \int_{\mathbb{S}^{n-1}} f^\infty(x, z) \, d\nu_x^\infty(z) \, d\lambda_\nu(x)$$

where f^∞ is the recession function defined as $f^\infty(x, z) := \lim_{\substack{x' \rightarrow x \\ z' \rightarrow z \\ t \rightarrow \infty}} \frac{f(x', tz')}{t}$.

In [20] a characterization theorem for generalized Young measures is proved. As in the case of classical Young measures, a necessary condition in the real-valued case for having a generalized gradient Young measure (i.e. generated by a sequence of gradients of functions that converge weakly-* in BV) is

$$\int_{\Omega} \int_{\mathbb{R}^n} |z| \, d\nu_x(z) \, dx + \lambda_\nu(\bar{\Omega}) < \infty$$

We refer to [20] for general results in the vectorial context of $BV(\mathbb{R}^n, \mathbb{R}^m)$. In Section 5 we recall the main results in the real-valued case $m = 1$.

The examples given in [1, 20], and those from Section 5, show that Young measures are totally suitable for describing the concentration and oscillations effects generated by the weak convergence of gradients. In fact, limit Young measures contain analytic and geometric information; they depend on the converging sequence (and not only on its weak limit!) so they carry some information about the weak limit of the sequence of gradients and the intrinsic features of the sequence.

Young varifolds We have now the material to introduce the Young varifolds, i.e. a suitable class of varifolds generated by Young measures which allows us to formalize our problem in the varifolds framework. ¹

For every $f \in C_c(G_{n-1}(\Omega))$ let

$$g : (x, z) \in \Omega \times \mathbb{R}^n \mapsto g(x, z) = |z|f(x, z^\perp)$$

where z^\perp is the element of $G_{n-1}(\Omega)$ perpendicular to z . It is easy to check that for every $k \in \mathbb{R}$ we have $(kz)^\perp = z^\perp$ (as elements of $G(n, n-1)$) so we get $g^\infty(x, z) = f(x, z^\perp)$.

A varifold V is a Young varifold if there exists a Young measure ν such that

$$\int_{G_{n-1}(\Omega)} f(x, S) dV_\nu(x, S) = \int_{\Omega} \int_{\mathbb{R}^n} |z|f(x, z^\perp) d\nu_x dx + \int_{\Omega} \int_{\mathbb{S}^{n-1}} f(x, z^\perp) d\nu_x^\infty d\lambda_\nu \quad (2)$$

for every $f \in C_c(G_{n-1}(\Omega))$. $V = V_\nu$ is called the Young varifold associated to ν .

The definition of a Young varifold is particularly explicit for smooth functions. If $u \in C^2(\Omega)$ we consider the Young measure $\nu = (\nu_x, \nu_x^\infty, \lambda_\nu)$ defined by

$$\nu_x = \delta_{\nabla u_x}, \quad \nu_x^\infty = 0, \quad \lambda_\nu = 0$$

and it follows that

$$\int_{G_{n-1}} f(x, S) dV_\nu(x, S) = \int_{\Omega} |\nabla u| f(x, (\nabla u)^\perp(x)) dx.$$

The mass of the varifold is defined by

$$\mu_{V_\nu}(E) = V_\nu(G_{n-1}(E)) = \int_E \int_{\mathbb{R}^n} |z| d\nu_x(z) dx + \lambda_\nu(\bar{E}) \quad \forall E \subseteq \Omega.$$

and the first variation is

$$\delta V_\nu(X) = \int_{G_{n-1}(\Omega)} \operatorname{div}_S X(x) dV_\nu(x, S) = \int_{\Omega} \int_{\mathbb{R}^n} |z| \operatorname{div}_{z^\perp} X d\nu_x(z) dx + \int_{\Omega} \int_{\mathbb{S}^{n-1}} \operatorname{div}_{z^\perp} X d\nu_x^\infty(z) d\lambda_\nu$$

We can now, as we did for sets, show how the usual notions for smooth functions can be extended to the framework of Young varifolds.

	$u \in C^2$	V_ν Young varifold
Mass	$ Du $	μ_{V_ν}
First variation	$\int_{\mathbb{R}^2} \nabla u \operatorname{div}_{\nabla u^\perp} X dx$	$\delta V_\nu(X) = \int_{G_{n-1}(\Omega)} \operatorname{div}_S X dV_\nu(x, S)$
Mean curvature vector	$-(\operatorname{div} \frac{\nabla u}{ \nabla u }) \frac{\nabla u}{ \nabla u }$	$\mathbf{H}_V = -\frac{\delta V_\nu}{\mu_{V_\nu}}$

¹M. Novaga kindly brought to our attention, while the current paper was in the final correction phase, the reference [6] where a generalization of Almgren's theory of varifolds in a Lorentzian setting is proposed. In a different context and for different purposes, it shares with our work the idea of disintegrating and indexing the measures that we borrowed from [20] while it is done using ad-hoc varifolds in [6].

Finally, we define the generalized Willmore energy associated with a Young varifold as

$$W(V) = \int_{\Omega} (1 + |\mathbf{H}_V|^p) d\mu_V.$$

The paper is devoted to defining carefully Young varifolds, exhibiting some of their properties and investigating the relationship between Young varifolds and the relaxation problems for F and W . Given a function $u \in \text{BV}$ such that $\bar{F}(u) < \infty$, we focus on the class $\mathbb{V}(u)$ of all Young varifolds V_v such that $\|\delta V_v\| \ll \mu_{V_v}$ and v is the limit of gradient Young measures $\nu_{\nabla u_n}$ where (u_n) converges weakly- $*$ to u in BV . Studying the Young varifolds in $\mathbb{V}(u)$ is somewhat delicate. In *dimension 2*, using the results of [24], we prove (Theorems 8.6 and 8.6, Corollary 8.14) that for every $u \in \text{SBV}$ with compact support and such that $\bar{F}(u) < \infty$, there exists $V \in \mathbb{V}(u)$ such that $W(V) = \bar{F}(u)$. We conjecture that a similar result holds in higher dimension but the proof remains so far out of reach. We shall comment this point later on. So far, we are able to prove in Theorem 8.1 that, *in any dimension ≥ 2 ,*

$$\bar{F}(u, \Omega) \geq \text{Min} \{W(V) : V \in \mathbb{V}(u)\}, \quad (3)$$

There is no hope that equality holds in general in (3) as arises from simple two-dimensional examples, see Remark 8.2 and Proposition 8.4. Therefore, what additional assumptions must be taken in $\mathbb{V}(u)$ to guarantee the equality? Clearly, in dimension 2, it follows from 8.6 that a necessary assumption is the existence of a tangent *everywhere* on the support of the concentration measure λ , see also [9]. In contrast, things are really unclear in higher dimension and are the purpose of ongoing research. It follows from the results of Menne in [26] that λ can be decomposed into $(n-1)$ -fibers whose supports are C^2 -rectifiable, but this regularity remains too weak even in dimension 2 (a tri-segment is C^2 -rectifiable but there is no tangent at the triple point). A more accurate characterization is needed, which has of course to do with the largely open problem of characterizing the boundaries of n -sets, $n \geq 3$, whose relaxed Willmore energy is finite.

Why do we believe that Young varifolds are the right tools for tackling the problem of representing \bar{F} in dimension higher than 2? Because they offer the possibility to carry all together and implicitly the concentration at the limit of the boundaries $\partial\{u \geq t\}$, using a unique representation of the general form $(\nu_x, \nu_x^\infty, \lambda)$, and because compactness and semi-continuity of the energy under constraints are obtained very easily (see Corollary 8.2). As for the information carried by Young varifolds, it must be emphasized from (2) that a Young varifold of $\mathbb{V}(u)$ for $u \in \text{BV}(\mathbb{R}^n)$ is a $(n-1)$ -varifold (it acts on $G_{n-1}(\Omega)$) but is not necessarily rectifiable: the support in \mathbb{R}^2 of the Young varifold associated with $u(x, y) = x$ is the whole plane. A Young varifold in $\mathbb{V}(u)$ must rather be seen as a *fiber bundle* whose fibers are $(n-1)$ -rectifiable varifolds.

Are there alternative approaches to the problem? It has been shown in [4] that the study of $\bar{F}(u)$ when u is *smooth* can be tackled considering explicitly all boundaries $\partial\{u \geq t\}$. Following [4, 24], let us examine whether the same strategy is applicable when u is possibly unsmooth. Take $u \in L^1(\mathbb{R}^n)$ and a sequence of smooth functions (u_h) converging to u in $L^1(\mathbb{R}^n)$ and such that $F(u_h) \rightarrow \bar{F}(u)$ as $h \rightarrow \infty$. Possibly extracting a subsequence, one can assume that for almost every t , $\{u_h > t\}$ converges to $\{u > t\}$ in measure. In addition, by Fatou's Lemma,

$$\int_{\mathbb{R}} \liminf_{h \rightarrow \infty} W(\{u_h > t\}) dt \leq \liminf_{h \rightarrow \infty} \int_{\mathbb{R}} W(\{u_h > t\}) dt = \bar{F}(u)$$

therefore $\liminf_{h \rightarrow \infty} W(\{u_h > t\}) < \infty$ is finite for almost every t . It follows that, for almost every t , the $(n-1)$ -dimensional varifolds with unit multiplicity $\mathbf{v}(\partial\{u_h > t\}, 1)$ form a sequence with uniformly bounded mass, and uniformly bounded curvature in L^p . Since $p > 1$,

by the properties of varifolds [28] and the stability of absolute continuity (see Example 2.36 in [3]), there exists a subsequence $\mathbf{v}(\partial\{u_{h_k} > t\}, 1)$ depending on t and a limit integral $(n-1)$ -varifold V_t such that

$$\int_{\mathbb{R}^n} (1 + |\mathbf{H}_{V_t}|^p) d\|V_t\| \leq \liminf_{h \rightarrow \infty} W(\{u_h > t\})$$

In addition, one can prove [4] that the support M_t of V_t contains $\partial^*\{u > t\}$ for almost every t . What could be the remaining steps to get a representation of $\bar{F}(u)$?

1. show, if possible, that the limit varifolds V_t are nested, i.e. $\text{int} V_t \subset \text{int} V_{t'}$ if $t > t'$, where $\text{int} V_t$ denotes the set enclosed (in the measure-theoretic sense) by the support of V_t . Again, observe that $\int_{\mathbb{R}^n} (1 + |\mathbf{H}_{V_t}|^p) d\|V_t\| \leq \liminf_{h \rightarrow \infty} W(\{u_h > t\})$.
2. build a sequence of smooth sets E_h^t (for a suitable dense set of values t) such that $\partial E_h^t \rightarrow M_t$ (being M_t the support of V_t) and $W(E_h^t) \rightarrow \int_{\mathbb{R}^2} (1 + |\mathbf{H}_{V_t}|^p) d\|V_t\|$. The varifolds V_t being nested, one could actually build E_h^t so that $E_h^t \subset E_h^{t'}$ if $t > t'$.
3. by a suitable smoothing of the sets E_h^t , build a smooth function \tilde{u}_h such that $F(\tilde{u}_h) \leq \int_{\mathbb{R}} W(E_h^t) dt + \frac{1}{h}$.
4. passing to the limit, possibly using a subsequence, show that \tilde{u}_h tends to u in L^1 and using the lower semicontinuity of \bar{F} , conclude that

$$\bar{F}(u) = \int_{\mathbb{R}} \int_{\mathbb{R}^n} (1 + |\mathbf{H}_{V_t}|^p) d\|V_t\| dt$$

which would be a nice representation formula. The delicate steps in this tentative proof are steps 1 and 2. It is in particular not clear at all whether the limit varifolds are nested. It would be an easy consequence of the existence of a subsequence (u_{h_k}) such that the varifolds $\mathbf{v}(\partial\{u_{h_k} > t\}, 1)$ converge to V_t for almost every t . But this is *false* in general as shown by a counterexample communicated to us by G. Savaré and fully described (Example 1.2) in the companion paper [24]. The example shows a sequence $\{\tilde{u}_n\} \subset C^0([0, 1]^2)$ with smooth level lines $\{\tilde{u}_n = t\}$ satisfying

$$\sup_n \int_{\mathbb{R}} \int_{\partial\{\tilde{u}_n(x) > t\} \cap (0, 1)^2} (1 + |\kappa_{\partial\{\tilde{u}_n(x) > t\} \cap (0, 1)^2}|^p) d\mathcal{H}^1 dt < \infty,$$

but such that there exists no subsequence $(t \mapsto \mathbf{v}(\partial\{u_{h_k} > t\}, 1))_k$ converging for almost every t to a limit varifold V_t .

In the particular case of dimension 2, we overcame this subsequence issue in [24] using the fact that the varifolds are supported on $W^{2,p}$ parametric curves. Then step 1 follows from the selection of countably many “shepherd” curves, that guide the remaining others, and a diagonal extraction argument that uses the C^1 convergence of the parametric curves. Having parametric curves is crucial for the smoothing step (step 2), and more precisely for moving apart the curves while controlling the energy.

Is the same strategy applicable to dimension greater than 2? The martingale argument that we used in [24] for the diagonal extraction is valid in any dimension, and the convergence of countably many C^1 curves can be replaced by the convergence of countably many integral varifolds, which, even being much weaker, is enough to obtain the limit structure. However, we do not know so far whether step 2 could be generalized to higher dimension.

It follows from Menne's results [26] that the limit varifolds are supported on C^2 -rectifiable sets but it is far from being clear how these countable coverings can be smoothly deformed while controlling the energy of the underlying set. Above all, we feel that the understanding of the problem could benefit from using a framework that is lighter than explicit unions of integral varifolds, that provides easily relative compactness and semicontinuity of the energy, and this motivated the introduction of Young varifolds.

The plan of the paper is as follows: the first sections are dedicated to a careful introduction of all notions that we have roughly described so far. More precisely, in Section 2 we recall the main definitions and results obtained in [24]. Section 3 and 4 are devoted, respectively, to a general class of functionals depending on measures and to the varifold theory. In Section 5 we recall a few facts about Young measures, following [20]. In Sections 6 and 7 we define the Young varifolds and their Willmore energy, and we provide several examples showing that Young varifolds allow to get information about geometric phenomena, like oscillations and concentration, for minimizing sequences. Lastly, we study in section 8 the relationship between \bar{F} and the Willmore functional for Young varifolds.

General notations

\mathbb{R}^n is equipped with the Euclidean norm and we will denote by either \mathcal{L}^n or $|\cdot|$ the Lebesgue measure on \mathbb{R}^n . \mathcal{H}^k is the k -dimensional Hausdorff measure. The restriction of a measure μ to a set A is denoted by $\mu \llcorner A$ and $\text{spt } \mu$ is the support of μ .

For two open sets $E, F \subset \mathbb{R}^n$ the notation $E \subset\subset F$ means that $\bar{E} \subset F$ and \bar{E} is compact.

If X is a locally compact separable metric space we denote by $\mathcal{M}(X, \mathbb{R}^n)$ the space of \mathbb{R}^n -valued bounded Radon measures and by $\mathcal{M}^+(X)$, $\mathcal{M}^1(X)$ the spaces of positive Radon measures and probability measures, respectively. Moreover, given $\mu \in \mathcal{M}(X, \mathbb{R}^n)$ and $\nu \in \mathcal{M}^+(X)$ we denote by $\frac{\mu}{\nu}$ the derivative of μ with respect to ν and the Radon-Nikodym decomposition of μ with respect to ν is $\mu = \mu^a + \mu^s = \frac{\mu}{\nu} \nu + \mu^s$.

$C_c, C^k, L^p, W^{k,p}, BV, SBV$ are the usual function spaces. For a detailed study of the spaces BV and SBV of functions with bounded variation, the reader may refer to [3]. If $\Omega \subset \mathbb{R}^n$, we say that $\partial\Omega \in C^k$ (resp. $W^{k,p}$) if we can represent locally its boundary as a graph of a C^k (resp. $W^{k,p}$) function. In particular, Ω is called a Lipschitz domain if $\partial\Omega \in C^{0,1}$.

2 Relaxation by a coarea-type formula in dimension 2

We recall in this section the main results proved in [24] which will be used in the following. Let us start with the notion of system of curves of class $W^{2,p}$:

Definition 2.1 *By a system of curves of class $W^{2,p}$ we mean a finite family $\Gamma = \{\gamma_1, \dots, \gamma_N\}$ of closed curves of class $W^{2,p}$ (and so C^1) admitting a parameterization (still denoted by γ_i) $\gamma_i \in W^{2,p}([0, 1], \mathbb{R}^2)$ with unit velocity. Moreover, every curve of Γ can have tangential self-contacts but without crossing and two curves of Γ can have tangential contacts but without crossing. In particular, $\gamma_i(t_1)$ and $\gamma_j(t_2)$ are parallel whenever $\gamma_i(t_1) = \gamma_j(t_2)$ for some $i, j \in \{1, \dots, N\}$ and $t_1, t_2 \in [0, 1]$.*

The trace (Γ) of Γ is the union of the traces (γ_i) , and the interior of the system Γ is

$$\text{Int}(\Gamma) = \{x \in \mathbb{R}^2 \setminus (\Gamma) : I(x, \Gamma) = 1 \pmod{2}\}, \quad \text{with } I(x, \Gamma) = \sum_{i=1}^N I(x, \gamma_i).$$

The multiplicity function Γ is $\theta_\Gamma : (\Gamma) \rightarrow \mathbb{N}$, $\theta(z) = \sharp\{\Gamma^{-1}(z)\}$, where \sharp is the counting measure. If the system of curves is the boundary of a set E with $\partial E \in C^2$, we simply denote it as ∂E .

Remark 2.2 Remark that, by previous definition, every $|\gamma'_i(t)|$ is constant for every $t \in [0, 1]$ so the arc-length parameter is given by $s(t) = tL_i$ where L_i is the length of γ_i . Denoting by $\tilde{\gamma}_i$ the curve parameterized with respect to the arc-length parameter we have

$$s \in [0, L_i], \tilde{\gamma}_i(s) = \gamma_i(s/L_i), \tilde{\gamma}_i''(s) = \frac{\gamma_i''(s)}{L_i^2}.$$

Now, the curvature \mathbf{k} as a function of s , satisfies $\mathbf{k} = \tilde{\gamma}_i''(s)$, which implies

$$\int_0^{L_i} (1 + |\tilde{\gamma}_i''(s)|^p) ds = \int_0^{L_i} (1 + |\mathbf{k}|^p) ds = \int_0^1 (|\gamma_i'(t)| + L_i^{1-2p} |\gamma_i''(t)|^p) dt.$$

Then, the condition $\gamma_i \in W^{2,p}([0, 1], \mathbb{R}^2)$ implies that $\tilde{\gamma}_i \in W^{2,p}([0, L_i], \mathbb{R}^2)$ and, for simplicity, in the sequel we denote by γ_i the curve parameterized with respect to the arc-length parameter.

In dimension 2, the Willmore functional for a system Γ of curves of class $W^{2,p}$ is

$$W(\Gamma) = \sum_{i=1}^N W(\gamma_i) = \sum_{i=1}^N \int_{(\gamma_i)} (1 + |\mathbf{k}_{\gamma_i}|^p) d\mathcal{H}^1.$$

Definition 2.3 We say that Γ is a limit system of curves of class $W^{2,p}$ if Γ is the weak limit of a sequence (Γ_h) of boundaries of bounded open sets with $W^{2,p}$ parameterizations.

The following class of curve-valued functions will be used for covering the level lines of a real function.

Definition 2.4 Let \mathcal{A} denote the class of functions

$$\Phi : t \in \mathbb{R} \rightarrow \Phi(t)$$

where for almost every $t \in \mathbb{R}$, $\Phi(t) = \{\gamma_t^1, \dots, \gamma_t^N\}$ is a limit system of curves of class $W^{2,p}$ and such that, for almost every $\underline{t}, \bar{t} \in \mathbb{R}$, $\underline{t} < \bar{t}$, the following conditions are satisfied:

- (i) $\Phi(\underline{t})$ and $\Phi(\bar{t})$ do not cross but may intersect tangentially;
- (ii) $\text{Int}(\Phi(\bar{t})) \subseteq \text{Int}(\Phi(\underline{t}))$ (pointwisely);
- (iii) if, for some i , $\mathcal{H}^1((\gamma_t^i) \setminus \overline{\text{Int}(\Phi(\underline{t}))}) \neq 0$ then

$$\mathcal{H}^1([\gamma_t^i \setminus \overline{\text{Int}(\Phi(\underline{t}))}] \setminus (\Phi(\underline{t}))) = 0.$$

Remark 2.5 One may remark that, from condition (ii) of Definition 2.4, for every curve $\gamma \in \Phi(\underline{t})$, $(\gamma) \cap \text{Int}(\Phi(\bar{t})) = \emptyset$. In fact if $x \in (\gamma) \cap \text{Int}(\Phi(\bar{t}))$ then $x \in \text{Int}(\Phi(\bar{t}))$ and $x \notin \text{Int}(\Phi(\underline{t}))$ which gives a contradiction with condition (ii).

Definition 2.6 (The class $\mathcal{A}(u)$) Let $u \in \text{BV}(\mathbb{R}^2)$. We define $\mathcal{A}(u)$ as the set of functions $\Phi \in \mathcal{A}$ such that, for almost every $t \in \mathbb{R}$, we have

$$(\Phi(t)) \supseteq \partial^* \{u > t\} \quad (\text{up to a } \mathcal{H}^1\text{-negligible set})$$

and

$$\{u > t\} = \text{Int}(\Phi(t)) \quad (\text{up to a } \mathcal{L}^2\text{-negligible set}).$$

In particular, if $u \in C^2(\mathbb{R}^2)$, we will denote as $\Phi[u]$ the function of $\mathcal{A}(u)$ defined as

$$t \mapsto \partial \{u > t\}.$$

In [24] we proved the following representation result for the relaxation problem for the Willmore functional on \mathbb{R}^2

Theorem 2.7 *Let $u \in \text{BV}(\mathbb{R}^2)$ with $\bar{F}(u, \mathbb{R}^2) < \infty$. Then $\bar{F}(u, \mathbb{R}^2) = \text{Min}_{\Phi \in \mathcal{A}(u)} G(\Phi)$.*

The next proposition points out the relationship between the relaxation problem on \mathbb{R}^2 for a function with compact support and the relaxation problem on a suitable $\Omega \subset \mathbb{R}^2$:

Proposition 2.8 *Let $u \in \text{BV}(\mathbb{R}^2)$ with compact support and such that $\bar{F}(u, \mathbb{R}^2) < \infty$. There exists an open bounded domain Ω such that*

$$\bar{F}(u, \mathbb{R}^2) = \bar{F}_B^0(u, \Omega) := \inf \left\{ \liminf_{h \rightarrow \infty} \int_{\Omega} |\nabla u_h| (1 + |\text{div} \frac{\nabla u_h}{|\nabla u_h|}|^p) dx : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\}.$$

As pointed out in [24] such a proposition is not true for the relaxation problem defined with C^2 instead of C_c^2 .

3 Functionals defined on measures

Let μ, ν be Radon measures on $\Omega \subset \mathbb{R}^n$, μ positive, ν \mathbb{R}^m -valued and let $f : \mathbb{R}^m \rightarrow [0, \infty]$ be convex. We set

$$G(\nu, \mu) = \int_{\Omega} f\left(\frac{\nu}{\mu}(x)\right) d\mu(x) + \int_{\Omega} f^{\infty}\left(\frac{\nu^s}{|\nu^s|}(x)\right) d|\nu^s|(x)$$

where ν^s is the singular part of ν with respect to μ and $f^{\infty} : \mathbb{R}^m \rightarrow \mathbb{R} \cup \{\infty\}$ is the recession function of f defined by

$$f^{\infty}(z) = \lim_{t \rightarrow \infty} \frac{f(z_0 + tz) - f(z_0)}{t} \quad (4)$$

where $z_0 \in \mathbb{R}^m$ is any vector such that $f(z_0) < \infty$.

As stated in the theorem below, G is lower semicontinuous under suitable assumptions.

Theorem 3.1 ([3], Thm 2.34) *Let Ω be an open subset of \mathbb{R}^n and ν, ν_h be \mathbb{R}^m -valued Radon measures on Ω , μ, μ_h positive Radon measures on Ω . Let $f : \mathbb{R}^m \rightarrow [0, \infty]$ be a convex lower semicontinuous function. If $\nu_h \xrightarrow{*} \nu$ and $\mu_h \xrightarrow{*} \mu$ in Ω then*

$$G(\nu, \mu) \leq \liminf_{h \rightarrow \infty} G(\nu_h, \mu_h).$$

Notice that if f has superlinear growth (i.e. $f^{\infty}(z) < \infty$ only if $z = 0$) then $G(\nu, \mu) < \infty$ only if $\nu \ll \mu$ and in this case

$$G(\nu, \mu) = \int_{\Omega} f\left(\frac{\nu}{\mu}(x)\right) d\mu(x).$$

The next theorem will be useful in the sequel and is a direct consequence of Theorem 3.1:

Proposition 3.2 ([3], Example 2.36) *Let Ω be an open subset of \mathbb{R}^n , $\nu, (\nu_h)$ \mathbb{R}^m -valued Radon measures on Ω , and $\mu, (\mu_h)$ positive Radon measures on Ω . Let $f : \mathbb{R}^m \rightarrow [0, \infty]$ be a convex lower semicontinuous function with superlinear growth. If $\nu_h \xrightarrow{*} \nu$, $\mu_h \xrightarrow{*} \mu$ in Ω , $\nu_h \ll \mu_h$ and $\int_{\Omega} f(\nu_h/\mu_h) d\mu_h$ is bounded then $\nu \ll \mu$ and*

$$G(\nu, \mu) \leq \liminf_{h \rightarrow \infty} G(\nu_h, \mu_h).$$

4 Varifolds

We collect below a few facts about varifolds. More details can be found in [28, 2].

4.1 Definitions

We consider $G(n, k)$, $k \leq n$, the set of all k -dimensional subspaces of \mathbb{R}^n equipped with the metric

$$\|S - T\| = \left(\sum_{i,j=1}^n |e_i \cdot P_S(e_j) - e_i \cdot P_T(e_j)|^2 \right)^{1/2} \quad \forall S, T \in G(n, k),$$

where P_S and P_T are the orthogonal projections of \mathbb{R}^n onto S and T , respectively, and $\{e_i\}_{i=1, \dots, n}$ is the canonical basis of \mathbb{R}^n . $G(n, k)$ is called the Grassmannian of all unoriented k -subspaces of \mathbb{R}^n .

For a subset Ω of \mathbb{R}^n we define $G_k(\Omega) = \Omega \times G(n, k)$ equipped with the product metric.

Definition 4.1 (Varifolds) *A k -varifold V on Ω is a Radon measure on $G_k(\Omega)$. The weight measure of V is the Radon measure on Ω defined by*

$$\mu_V(U) = V(\pi^{-1}(U))$$

where π is the projection $(x, S) \mapsto x$ of $G_k(\Omega)$ onto \mathbb{R}^n .

A very important class of varifolds is obtained from rectifiable sets.

Definition 4.2 (Countably C^r - k -rectifiable sets) *$M \subseteq \mathbb{R}^n$ is a countably C^r - k -rectifiable set ($r \geq 1$) if*

$$M = M_0 \cup \left(\bigcup_{i=1}^{+\infty} K_i \right)$$

where $\mathcal{H}^k(M_0) = 0$, $K_i \cap K_j = \emptyset$ if $i \neq j$ and for all $i \geq 1$ K_i is a subset of a C^r - k -manifold of \mathbb{R}^n .

M is C^r - k -rectifiable if M is countably C^r - k -rectifiable and $\mathcal{H}^k(M) \leq +\infty$.

M is (countably) C^r - k -rectifiable in $\Omega \subseteq \mathbb{R}^n$ if $M \cap \Omega$ is (countably) C^r - k -rectifiable.

Remark that if M is a countably C^r - k -rectifiable set then for every $x \in K_i$ we can consider the tangent plan to K_i at x , denoted by T_x , and, by the previous definition, the function

$$x \mapsto T_x$$

is defined for \mathcal{H}^k -a.e. $x \in M$.

Definition 4.3 (Rectifiable and integral varifolds) *V is a rectifiable k -varifold if there exists a C^r - k -rectifiable subset M of Ω ($r \geq 1$) such that*

$$V = \theta \mathcal{H}^k \llcorner M \otimes \delta_{T_x}$$

where θ is a positive \mathcal{H}^k -locally integrable function on M called multiplicity of V . Then we denote $V = \mathbf{v}(M, \theta)$ and the weight measure of V is

$$\mu_V(U) = \int_{M \cap U} \theta(x) d\mathcal{H}^k(x).$$

If $\theta(M) \subset \mathbb{N}$ then $\mathbf{v}(M, \theta)$ is called an integral varifold.

4.2 First variation and generalized mean curvature

The first variation of a k -varifold V is the functional given by

$$\delta V : C_c(\Omega, \mathbb{R}^n) \rightarrow \mathbb{R}$$

$$\delta V(X) = \int_{G_k(\Omega)} \operatorname{div}_S X(x) dV(x, S),$$

where div_S is the tangential divergence with respect to S .

Definition 4.4 *A k -varifold is called a Allard's varifold if it has locally bounded first variation in Ω , i.e. for each $W \subset\subset \Omega$ there exists a constant $0 < C < \infty$ such that*

$$|\delta V(X)| \leq C \|X\|_{L^\infty(W)} \quad \forall X \in C_c(W, \mathbb{R}^n).$$

If V is a Allard's varifold then $\|\delta V\|(W) = \sup\{|\delta V(X)| : X \in C_c(W, \mathbb{R}^n), \|X\|_{L^\infty(W)} \leq 1\} < \infty$ for each $W \subset\subset \Omega$ so, by the Riesz representation theorem,

$$\delta V(X) = - \int_{\Omega} \langle X, \nu \rangle d\|\delta V\|$$

where $\|\delta V\|$ is the total variation measure of δV and ν is a $\|\delta V\|$ -measurable \mathbb{R}^n -valued function with $|\nu| = 1$ $\|\delta V\|$ -a.e in Ω . By the Radon-Nikodym decomposition theorem,

$$\|\delta V\| = \frac{\|\delta V\|}{\mu_V} \mu_V + \sigma$$

where the derivative of $\|\delta V\|$ with respect to μ_V exists μ_V -a.e. and the measure σ , the singular part of $\|\delta V\|$ with respect to μ_V , is supported on Z such that

$$Z = \left\{ x \in \Omega : \frac{\|\delta V\|}{\mu_V}(x) = +\infty \right\}, \quad \mu_V(Z) = 0.$$

So, defining $\mathbf{H}_V(x) = \frac{\|\delta V\|}{\mu_V}(x) \nu(x) = -\frac{\delta V}{\mu_V}(x)$, we can write

$$\delta V(X) = - \int_{\Omega} \langle X, \mathbf{H}_V \rangle d\mu_V - \int_Z \langle X, \nu \rangle d\sigma$$

for all $X \in C_c(\Omega, \mathbb{R}^n)$.

Definition 4.5 *With the definitions above, \mathbf{H}_V is the generalized mean curvature of V , Z the generalized boundary of V , σ the generalized boundary measure of V , and $\nu|_Z$ the generalized unit conormal of V .*

Remark 4.6 Notice that if V is a rectifiable k -varifold $\mathbf{v}(M, 1)$ associated with M a C^2 -manifold without boundary then, from the divergence theorem for manifolds (see [3]: Theorem 7.34), $\|\delta V\| \ll \mu_V$ and the mean curvature \mathbf{H}_V coincides everywhere out of a \mathcal{H}^k -negligible set with the classical mean curvature of M .

Remark 4.7 (2-Varifolds supported on $W^{2,p}$ -curves) Let $V = \mathbf{v}(M, \theta)$ be the varifold on \mathbb{R}^2 associated with M a closed curve in \mathbb{R}^2 of class $W^{2,p}$ with $p > 1$, and with the density function θ . M admits a parametrization (still denoted by M) $M \in W^{2,p}([0, L], \mathbb{R}^2)$,

$$M(s) = (f(s), g(s)), \quad f, g \in W^{2,p}([0, L], \mathbb{R})$$

where s is the arc-length parameter and L is the length of the curve M . Then, by direct calculation, we will show that $\|\delta V\| \ll \mu_V$ and the mean curvature of V is a function of the weak second derivatives of f and g . This fact can be generalized using Hutchinson's varifolds [17, 16].

Consider $X \in C_c^1(\mathbb{R}^2, \mathbb{R}^2)$, $X(x) = (X^1(x), X^2(x))$, $\{e_1, e_2\}$ the canonical orthonormal basis of \mathbb{R}^2 and denote by $\langle \cdot, \cdot \rangle$ the usual scalar product in \mathbb{R}^2 . Then

$$\begin{aligned} \operatorname{div}_M X(M(s)) &= \langle e_1, \langle \nabla X^1(M(s)), M'(s) \rangle M'(s) \rangle + \langle e_2, \langle \nabla X^2(M(s)), M'(s) \rangle M'(s) \rangle = \\ &= f'(s) \langle \nabla X^1(M(s)), M'(s) \rangle + g'(s) \langle \nabla X^2(M(s)), M'(s) \rangle \end{aligned}$$

and

$$\begin{aligned} \delta V(X) &= \int_M \theta \operatorname{div}_M X \, d\mathcal{H}^1 = \int_0^L [f'(s) \langle \nabla X^1(M(s)), M'(s) \rangle + g'(s) \langle \nabla X^2(M(s)), M'(s) \rangle] \, ds \\ &= \int_0^L \left[f'(s) \frac{d}{ds} [X^1(M(s))] + g'(s) \frac{d}{ds} [X^2(M(s))] \right] \, ds. \end{aligned}$$

Now, integrating by parts and using the facts that X has compact support, M is closed and $f, g \in W^{2,p}([0, L], \mathbb{R})$, we get $\delta V(X) = - \int_0^L \langle X(M(s)), (f''(s), g''(s)) \rangle \, ds$, where f'', g'' are the weak second derivatives. It follows that $\delta V(X) = - \int_M \langle X, \mathbf{H}_V \rangle \theta \, d\mathcal{H}^1$ where the curvature of varifold V is given by $\mathbf{H}_V(p) = M''(M^{-1}(p)) = (f''(M^{-1}(p)), g''(M^{-1}(p))) \, \forall p \in (M)$. Clearly $\|\delta V\| \ll \mu_V$. By a similar calculation we can generalize this remark to the varifolds $V = \mathbf{v}(M, \theta)$ where M is a system of curves of class $W^{2,p}$ and θ the density function on M .

5 Young measures

We collect below a few facts about Young measures, following [20].

5.1 Definitions and general results

Let Ω be a bounded Lipschitz domain of \mathbb{R}^n and let $f \in C(\Omega \times \mathbb{R}^n)$. By \mathbb{B}^n we denote the open unit ball in \mathbb{R}^n and $\mathbb{S}^{n-1} = \partial \mathbb{B}^n$. We consider the following operator

$$\begin{aligned} T : C(\Omega \times \mathbb{R}^n) &\rightarrow C(\Omega \times \mathbb{B}^n) \\ Tf(x, z) &:= (1 - |z|)f\left(x, \frac{z}{1 - |z|}\right) \end{aligned}$$

and the property

$$Tf \text{ extends into a bounded continuous function on } \overline{\Omega \times \mathbb{B}^n}. \quad (5)$$

We can define the Banach space $(\mathbf{E}(\Omega; \mathbb{R}^n), \|\cdot\|_{\mathbf{E}})$, where

$$\mathbf{E}(\Omega; \mathbb{R}^n) = \{f \in C(\Omega \times \mathbb{R}^n) : f \text{ satisfies (5)}\}$$

$$\|f\|_{\mathbf{E}} = \|Tf\|_{L^\infty(\overline{\Omega \times \mathbb{B}^n})}.$$

For example, a continuous function which is either uniformly bounded or positively 1-homogeneous in its second argument (i.e. $f(x, sz) = sf(x, z)$, for all $s \geq 0$) belongs to $\mathbf{E}(\Omega \times \mathbb{R}^n)$. Moreover, every $f \in \mathbf{E}(\Omega; \mathbb{R}^n)$ has linear growth to infinity since

$$|f(x, z)| = (1 + |z|)Tf\left(x, \frac{z}{1 + |z|}\right) \leq \|f\|_{\mathbf{E}}(1 + |z|) \quad \text{for all } x \in \Omega, z \in \mathbb{R}^n.$$

For all $f \in \mathbf{E}(\Omega \times \mathbb{R}^n)$ we define the recession function $f^\infty : \bar{\Omega} \times \mathbb{S}^{n-1} \rightarrow \mathbb{R}$ by

$$f^\infty(x, z) := \lim_{\substack{x' \rightarrow x \\ z' \rightarrow z \\ t \rightarrow \infty}} \frac{f(x', tz')}{t}.$$

Remark that for every convex function $f = f(z)$ belonging to $\mathbf{E}(\Omega; \mathbb{R}^n)$ the previous definition coincides with (4) (this follows from continuity for convex functions and taking $z_0 = 0$ in (4)).

Before defining generalized Young measures it is convenient to recall some notations about parametrized measures. For sets $E \subset \mathbb{R}^k$, $F \subset \mathbb{R}^l$ open or closed, a parametrized measure $(\nu_x)_{x \in E}$ is a mapping from E to $\mathcal{M}(F)$, the set of Radon measures on F . It is said to be weakly* μ -measurable, for some $\mu \in \mathcal{M}^+(E)$, if the function $x \mapsto \nu_x(B)$ is μ -measurable for all Borel sets $B \subset F$. Here μ -measurability is the measurability with respect to the μ -completion of the Borel σ -algebra on E .

Let $L_{w^*}^\infty(E, \mu, \mathcal{M}(F))$ denote the set of weakly* μ -measurable parametrized measures $(\nu_x)_{x \in E} \subset \mathcal{M}(F)$ such that $\sup_{x \in E} |\nu_x|(F) < \infty$ (taking the essential supremum with respect to μ). We will omit μ in the notation if it is the Lebesgue measure.

Definition 5.1 ([20]) *The set $\mathbf{Y}(\Omega, \mathbb{R}^n)$ of all generalized Young measures is the set of all triplets $(\nu_x, \lambda_\nu, \nu_x^\infty)$, simply written ν , such that :*

- (i) $\nu_x \in L_{w^*}^\infty(\Omega, \mathcal{M}^1(\mathbb{R}^n))$ where the map $x \mapsto \nu_x$ is defined up to a \mathcal{L}^n -negligible set and with $x \mapsto \langle \nu_x, |\cdot| \rangle \in L^1(\Omega)$. ν_x is called *oscillation measure*.
- (ii) $\lambda_\nu \in \mathcal{M}^+(\bar{\Omega})$. λ_ν is called *concentration measure*.
- (iii) $\nu_x^\infty \in L_{w^*}^\infty(\bar{\Omega}, \lambda_\nu; \mathcal{M}^1(\mathbb{S}^{n-1}))$ where the map $x \mapsto \nu_x^\infty$ is defined up to a λ_ν -negligible set. ν_x^∞ is called *concentration-angle measure*.

Therefore we can see $\mathbf{Y}(\Omega, \mathbb{R}^n)$ as a subset of $\mathbf{E}(\Omega \times \mathbb{R}^n)^*$ through the following duality pairing :

$$\langle \langle \nu, f \rangle \rangle := \int_{\Omega} \int_{\mathbb{R}^n} f(x, z) d\nu_x(z) dx + \int_{\bar{\Omega}} \int_{\mathbb{S}^{n-1}} f^\infty(x, z) d\nu_x^\infty(z) d\lambda_\nu(x)$$

Then we can define the convergence for Young measures in the sense of duality:

Definition 5.2 (Y-convergence) *A sequence $\{\nu_h\} \subset \mathbf{Y}(\Omega, \mathbb{R}^n)$ converges weakly* to ν in $\mathbf{Y}(\Omega, \mathbb{R}^n)$, written $\nu_h \xrightarrow{\mathbf{Y}} \nu$, if $\langle \langle \nu_h, f \rangle \rangle \rightarrow \langle \langle \nu, f \rangle \rangle$ for all $f \in \mathbf{E}(\Omega \times \mathbb{R}^n)$.*

Moreover, we have the following properties :

Theorem 5.3 (Closure, [20], Cor. 1) *The set $\mathbf{Y}(\Omega, \mathbb{R}^n)$ is weakly* closed (as a subset of $\mathbf{E}(\Omega \times \mathbb{R}^n)^*$).*

Theorem 5.4 (Compactness, [20], Cor. 2) *Let $\{\nu_h\} \subset \mathbf{Y}(\Omega, \mathbb{R}^n)$ be a sequence such that :*

- (i) *the functions $x \mapsto \int_{\mathbb{R}^n} |\cdot| d\nu_h|_x$ are uniformly bounded in $L^1(\Omega)$;*
- (ii) *the sequence $\{\lambda_{\nu_h}(\bar{\Omega})\}$ is uniformly bounded.*

Then $\{\nu_h\}$ is weakly sequentially relatively compact in $\mathbf{Y}(\Omega, \mathbb{R}^n)$.*

Every Radon measure on $\bar{\Omega}$ can be associated with a Young measure:

Definition 5.5 Let $\mu \in \mathcal{M}(\bar{\Omega}, \mathbb{R}^n)$ with Radon-Nikodym decomposition $\mu = \alpha \mathcal{L}^n \llcorner \Omega + \mu_s$. The Young measure ν_μ associated with μ is defined by :

$$\nu_x = \delta_{\alpha(x)}, \quad \lambda_\nu = |\mu_s|, \quad \nu_x^\infty = \delta_{\frac{\mu_s}{|\mu_s|}}$$

Lastly, there exists a useful notion of barycenter for Young measures:

Definition 5.6 (Barycenter) The barycenter of $\nu \in \mathbf{Y}(\Omega, \mathbb{R}^n)$ is the measure $\text{Bar}_\nu \in \mathcal{M}(\bar{\Omega}, \mathbb{R}^n)$ given by

$$\text{Bar}_\nu = \left(\int_{\mathbb{R}^n} z \, d\nu_x \right) \mathcal{L}^n \llcorner \Omega + \left(\int_{\mathbb{S}^{n-1}} z \, d\nu_x^\infty \right) \lambda_\nu.$$

5.2 Gradient Young measures

Definition 5.7 The Young measure associated with $u \in \text{BV}(\Omega)$ is the measure $\nu_{Du(x)} = (\nu_x, \lambda_\nu, \nu_x^\infty)$ with

$$\nu_x = \delta_{\nabla u(x)}, \quad \lambda_\nu = |D^s u|, \quad \nu_x^\infty = \delta_{\frac{D^s u}{|D^s u|}(x)}.$$

Gradient Young measures can now be defined, see [20].

Definition 5.8 We call $\nu \in \mathbf{Y}(\Omega, \mathbb{R}^n)$ a gradient Young measure if there exists a bounded sequence $\{u_h\} \subset \text{BV}(\Omega)$ (called a generating sequence) such that $\nu_{Du_h} \xrightarrow{\mathbf{Y}} \nu$. The set of gradient Young measures is denoted as $\mathbf{GY}(\Omega, \mathbb{R}^n)$.

Remark in particular that if ν is generated by $\{u_h\} \subset \text{BV}(\Omega)$, i.e. $\nu_{Du_h} \xrightarrow{\mathbf{Y}} \nu$, then for all $f \in \mathbf{E}(\Omega \times \mathbb{R}^n)$ we have

$$\begin{aligned} \lim_{h \rightarrow \infty} \langle \langle \nu_{Du_h}, f \rangle \rangle &= \lim_{h \rightarrow \infty} \left[\int_{\Omega} f(\nabla u(x)) \, dx + \int_{\Omega} f^\infty \left(x, \frac{D^s u}{|D^s u|}(x) \right) d|D^s u|(x) \right] = \\ &= \langle \langle \nu, f \rangle \rangle = \int_{\Omega} \int_{\mathbb{R}^n} f(x, z) \, d\nu_x(z) \, dx + \int_{\Omega} \int_{\mathbb{S}^{n-1}} f^\infty(x, z) \, d\nu_x^\infty(z) \, d\lambda_\nu(x). \end{aligned}$$

We will use a few connections shown in [20] between general gradient Young measures and BV functions:

Proposition 5.9

1. Given $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^n)$, all generating sequences $(u_h) \subset \text{BV}(\Omega)$ converge weakly-* in BV to $u \in \text{BV}(\Omega)$ such that $Du = \text{Bar}_\nu \llcorner \Omega$ (u is called an **underlying deformation**).
2. If $\{u_h\} \subset \text{BV}(\Omega, \mathbb{R})$ is uniformly bounded in BV, there exists a subsequence (not re-labeled) such that $u_h \rightarrow u$ weakly-* in BV and $\nu_{Du_h} \xrightarrow{\mathbf{Y}} \nu$ for some $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^n)$ with $Du = \text{Bar}_\nu \llcorner \Omega$. In general, ν may not coincide with ν_{Du} .
3. If $u_h \rightarrow u$ strictly in $\text{BV}(\Omega)$ then $\nu_{Du_h} \xrightarrow{\mathbf{Y}} \nu_{Du}$.

The proof of $Du = \text{Bar}_\nu \llcorner \Omega$ in 2. is easy but instructive. Testing the Young convergence with $f(x, z) = \langle g(x), z \rangle$ where $g \in C_c^\infty(\Omega, \mathbb{R}^n)$ (thus $f^\infty = f$) yields

$$\begin{aligned} \lim_{h \rightarrow \infty} \langle \langle \nu_{Du_h}, f \rangle \rangle &= \lim_{h \rightarrow \infty} \left[\int_{\Omega} \langle g(x), \nabla u(x) \rangle \, dx + \int_{\Omega} \langle g(x), \frac{D^s u}{|D^s u|}(x) \rangle d|D^s u|(x) \right] \\ &= \lim_{h \rightarrow \infty} \int_{\Omega} \langle g(x), dDu_h(x) \rangle \end{aligned}$$

and then, taking the limit, $\langle\langle v, f \rangle\rangle = \int_{\Omega} \langle g(x), dDu(x) \rangle$. Now, because of the choice of f , $\langle\langle v, f \rangle\rangle = \int_{\Omega} \langle g(x), d\text{Bar}_v \rangle$ so

$$Du = \text{Bar}_v \llcorner \Omega = \left(\int_{\mathbb{R}^n} z dv_x \right) \mathcal{L}^n \llcorner \Omega + \left(\int_{\mathbb{S}^{n-1}} z dv_x^\infty \right) \lambda_v \llcorner \Omega.$$

The Radon-Nikodym decomposition of λ_v with respect to \mathcal{L}^n implies

$$\lambda_v \llcorner \Omega = \frac{\lambda_v}{\mathcal{L}^n}(x) \mathcal{L}^n \llcorner \Omega + \lambda_v^s \llcorner \Omega \quad (6)$$

therefore

$$\begin{aligned} \nabla u(x) &= \int_{\mathbb{R}^n} z dv_x + \frac{\lambda_v}{\mathcal{L}^n}(x) \int_{\mathbb{S}^{n-1}} z dv_x^\infty \quad \mathcal{L}^n\text{-a.e. } x \in \Omega \\ D^s u &= \left(\int_{\mathbb{S}^{n-1}} z dv_x^\infty \right) \lambda_v^s \llcorner \Omega \quad \text{and} \quad \int_{\mathbb{S}^{n-1}} z dv_x^\infty \neq 0 \quad |D^s u|\text{-a.e. } x \in \Omega \end{aligned} \quad (7)$$

We end this section with the Characterization Theorem for gradient Young measures, that we state in the specific form of the real-valued case, see [20, Thm 9] for the more general form, and [20, p.542] as well as [20, Remark 8] for a justification of the simplification.

Theorem 5.10 (Characterization, [20], Thm 9) *Let $\Omega \subset \mathbb{R}^n$ be an open bounded Lipschitz domain. Then, a Young measure $\nu \in \mathbf{Y}(\Omega, \mathbb{R}^n)$ satisfying*

$$\lambda_\nu(\partial\Omega) = 0$$

is a gradient Young measure, i.e. $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^n)$, if and only if

$$\int_{\Omega} \int_{\mathbb{R}^n} |z| dv_x(z) dx + \lambda_\nu(\Omega) < \infty$$

and there exists $u \in \text{BV}(\Omega)$ such that $\text{Bar}_\nu = Du$, i.e. $Du = \langle \text{id}, \nu_x \rangle \mathcal{L}^n \llcorner \Omega + \langle \text{id}, \nu_x^\infty \rangle \lambda_\nu$.

5.3 Identification of gradient Young measures

We recall, following [1, 20], the classical techniques for the identification of a gradient Young measure ν . If $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^n)$, there exists a bounded sequence $\{u_h\} \subset \text{BV}(\Omega)$ such that $\nu_{Du_h} \xrightarrow{\mathbf{Y}} \nu$.

1) identification of ν_x : test the Young convergence using

$$f(x, z) = \Phi(x) \varphi(z)$$

with $\Phi \in L^\infty(\Omega)$ and $\varphi \in C_0(\mathbb{R}^n)$. Then $f^\infty = 0$ (because $\varphi^\infty = 0$) and we get

$$\varphi(\nabla u_h) \rightharpoonup \int_{\mathbb{R}^n} \varphi(z) dv_x(z) \quad \text{in } L^1(\Omega).$$

Using this fact for all such φ , we can identify ν_x .

An important particular situation is when $\nabla u_h \rightarrow \nu$ \mathcal{L}^n -a.e. for some $\nu \in L^1(\Omega)$ then, by the Dominated Convergence Theorem, we get $\varphi(\nabla u_h) \rightarrow \varphi(\nu)$ in $L^1(\Omega)$ and therefore

$$\varphi(\nabla u_h) \rightharpoonup \varphi(\nu) \quad \text{in } L^1(\Omega).$$

Therefore, if $\nabla u_h \rightarrow \nu$ a.e. then $\nu_x = \delta_{\nu(x)}$ for \mathcal{L}^n -a.e. $x \in \Omega$.

2) identification of λ_ν and ν_x^∞ : test the Young convergence using the function

$$f(x, z) = \Phi(x) |z| \varphi \left(x, \frac{z}{|z|} \right)$$

with $\Phi \in C(\overline{\Omega})$ and $\varphi \in C(\mathbb{S}^{n-1})$. Then $f^\infty = \varphi$ and we have

$$\begin{aligned} & \int_{\Omega} \Phi(x) |\nabla u_h(x)| \varphi \left(\frac{\nabla u_h(x)}{|\nabla u_h(x)|} \right) dx + \int_{\Omega} \Phi(x) \varphi \left(\frac{D^s u_h}{|D^s u_h|}(x) \right) d|D^s u_h|(x) \\ & \longrightarrow \int_{\Omega} \int_{\mathbb{R}^n} \Phi(x) |z| \varphi \left(\frac{z}{|z|} \right) d\nu_x(z) dx + \int_{\Omega} \int_{\mathbb{S}^{n-1}} \Phi(x) \varphi(z) d\nu_x^\infty(z) d\lambda_\nu(x) \end{aligned}$$

The knowledge from 1) and testing with all such Φ, φ allows to identify λ_ν and ν_x^∞ .

In particular taking $\varphi = 1$ so $f(x, z) = \Phi(x) |z|$, with $\Phi \in C(\overline{\Omega})$, we get

$$\int_{\Omega} |\nabla u_h(x)| \Phi(x) dx + \int_{\Omega} \Phi(x) d|D^s u_h|(x) \rightarrow \int_{\Omega} \int_{\mathbb{R}^n} |z| \Phi(x) dx + \int_{\Omega} \Phi(x) \lambda_\nu(x)$$

so

$$|Du_h| \xrightarrow{*} \left(\int_{\mathbb{R}^n} |z| d\nu_x(z) \right) \mathcal{L}^n \llcorner \Omega + \lambda_\nu, \quad \text{in } \mathcal{M}^+(\overline{\Omega}). \quad (8)$$

We now illustrate on a few classical examples (see the one-dimensional counterparts in [1]) what kind of information can be carried by gradient Young measures. We will revisit later on these examples within the framework of Young varifolds.

Example 5.11 (Oscillations). Let $n = 2$, $\Omega = B(0, 1)$ and

$$u_h(x) = \begin{cases} |x| - \frac{2k}{2^h} & \text{if } |x| \in \left[\frac{2k}{2^h}, \frac{2k+1}{2^h} \right] \\ -|x| + \frac{2k+2}{2^h} & \text{if } |x| \in \left[\frac{2k+1}{2^h}, \frac{2k+2}{2^h} \right] \end{cases} \quad \text{for } k = 0, \dots, 2^{h-1} - 1$$

Figure 3: A radial section of the graph of u_h

Since $\{u_h\}$ is uniformly bounded in $BV(\Omega)$, extracting a subsequence (not relabeled) yields $\nu_{Du_h} \xrightarrow{Y} \nu$ where $\nu_{Du_h} = (\nu_x^h, \lambda_\nu^h, \nu_x^{\infty, h})$ is defined by

$$\nu_x^h = \delta_{\nabla u_h(x)}, \quad \lambda_\nu^h = 0, \quad \nu_x^{\infty, h} \text{ is arbitrary.}$$

Testing the Young convergence first with $f(x, z) = \Phi(x) \varphi(z)$, where $\Phi \in C(\overline{\Omega})$ and $\varphi \in C_0(\mathbb{R}^n)$, and using polar coordinates and the Mean Value Theorem, then testing with $f(x, z) = \Phi(x) |z|$, it can be proved that

$$\nu_x = \frac{1}{2} \delta_{\frac{x}{|x|}} + \frac{1}{2} \delta_{-\frac{x}{|x|}}, \quad \lambda_\nu = 0, \quad \nu_x^\infty \text{ is arbitrary.}$$

Example 5.12 (Concentration). Let $n = 2$, $\Omega = B(0, 2)$ and

$$u_h(x) = \begin{cases} h(|x| - 1) & \text{if } |x| \in [1, 1 + \frac{1}{h}] \\ h(1 - |x|) & \text{if } |x| \in [1 - \frac{1}{h}, 1] \\ 0 & \text{otherwise} \end{cases}$$

Figure 4: A radial section of the graph of u_h

It is easily seen that $\{u_h\}$ is uniformly bounded in $BV(\Omega)$ thus, possibly after extracting a subsequence (not relabeled), $v_{Du_h} \xrightarrow{Y} v$. Testing the Young convergence first with $f(x, z) = |z|$, then with $f(x, z) = \Phi(x)|z||\varphi(z/|z|)$ where $\Phi \in C(\bar{\Omega})$ and $\varphi \in C(\mathbb{S}^1)$, it can be proved that

$$v_x = \delta_0, \quad \lambda_v = 4\mathcal{H}^1 \llcorner \partial B(0, 1), \quad v_x^\infty = \frac{1}{2}\delta_{\frac{x}{|x|}} + \frac{1}{2}\delta_{-\frac{x}{|x|}}.$$

Example 5.13 (Diffuse concentration). Let $n = 2$, $\Omega = B(0, 1)$ and

$$u_h(x) = \begin{cases} h\left(|x| - \frac{k}{h}\right) & \text{if } |x| \in \left[\frac{k}{h}, \frac{k}{h} + \frac{1}{2h^2}\right] \\ h\left(\frac{k}{h} + \frac{1}{2h^2} - |x|\right) & \text{if } |x| \in \left[\frac{k}{h} + \frac{1}{2h^2}, \frac{k}{h} + \frac{1}{h^2}\right] \\ 0 & \text{otherwise} \end{cases} \quad \text{where } k = 0, \dots, h-1.$$

Figure 5: A radial section of the graph of u_h

$\{u_h\}$ is clearly bounded in $BV(\Omega)$ so, possibly after the extraction of a subsequence (not relabeled), $v_{Du_h} \xrightarrow{Y} v$. Testing the Young convergence first with $f(x, z) = |z|$, then with $f(x, z) = \Phi(x)|z||\varphi(z/|z|)$, where $\Phi \in C(\bar{\Omega})$ and $\varphi \in C(\mathbb{S}^1)$, it can be proved that

$$v_x = \delta_0, \quad \lambda_v = \mathcal{L}^2 \llcorner \Omega, \quad v_x^\infty = \frac{1}{2}\delta_{\frac{x}{|x|}} + \frac{1}{2}\delta_{-\frac{x}{|x|}}.$$

This example shows that diffusion phenomena can also be generated by sequences converging to zero.

More generally, all previous examples illustrate that the limit gradient Young measure is not determined by the BV limit function but rather by the kind of sequence that generates it.

6 Young varifolds

In this section, Young varifolds are defined and their basic properties are studied.

Definition 6.1 (Young varifolds) *Let Ω be a bounded Lipschitz domain and let V be a $(n-1)$ -varifold. We say that V is a Young varifold if there exists $\nu \in \mathbf{Y}(\Omega, \mathbb{R}^n)$ such that*

$$V(E \times A) = \int_E \int_{\{z \in \mathbb{R}^n : z^\perp \in A\}} |z| d\nu_x(z) dx + \int_{\bar{E}} \nu_x^\infty(\{z \in \mathbb{S}^{n-1} : z^\perp \in A\}) d\lambda_\nu$$

for every $E \times A \subseteq G_{n-1}(\Omega)$, where z^\perp is the element of $G(n, n-1)$ perpendicular to the space spanned by z . Then V is denoted by V_ν and is called Young varifold associated with ν .

The weight measure is given by

$$\mu_{V_\nu}(E) = V_\nu(E \times G(n, n-1)) = \int_E \int_{\mathbb{R}^n} |z| d\nu_x(z) dx + \lambda_\nu(\bar{E}) \quad \forall E \subseteq \Omega.$$

We denote by $\mathbf{YV}(\Omega, \mathbb{R}^n)$ the class of Young varifolds.

Remark that, for every $f \in C_c(G_{n-1}(\Omega))$ the function $g(x, z) = |z|f(x, z^\perp)$ belongs to $\mathbf{E}(\Omega, \mathbb{R}^n)$. Moreover, as for every $s \in \mathbb{R}$ the linear spaces $(sz)^\perp$ and z^\perp represent the same element of $G(n, n-1)$, g is continuous and positively 1-homogeneous in z and it is easy to check that $g^\infty = f$. Thus we have $\int_{G_{n-1}(\Omega)} f(x, S) dV_\nu(x, S) = \langle \langle \nu, |z|f(x, z^\perp) \rangle \rangle \quad \forall f \in C_c(G_{n-1}(\Omega))$.

As was mentioned in the introduction, V_ν may not be a rectifiable varifold since its projection on Ω might be a n -measure whereas the tangent measure lives in $G(n, n-1)$.

The following proposition shows that the convergence of Young measures implies the convergence of the associated Young varifolds:

Proposition 6.2 *If $\nu_h \xrightarrow{\mathbf{Y}} \nu$ then $V_{\nu_h} \xrightarrow{*} V_\nu$.*

Proof : Given $f \in C_c(G_{n-1}(\Omega))$, the Young convergence is tested with $g(x, z) = |z|f(x, z^\perp) \in \mathbf{E}(\Omega; \mathbb{R}^n)$. Then if $\nu_h \xrightarrow{\mathbf{Y}} \nu$ we have

$$\int_{G_{n-1}(\Omega)} f dV_{\nu_h} = \langle \langle g, \nu_h \rangle \rangle \rightarrow \langle \langle g, \nu \rangle \rangle = \int_{G_{n-1}(\Omega)} f dV_\nu \quad \forall f \in C_c(G_{n-1}(\Omega))$$

so $V_{\nu_h} \xrightarrow{*} V_\nu$. □

Next proposition provides a sufficient condition for compactness in $\mathbf{YV}(\Omega, \mathbb{R}^n)$.

Proposition 6.3 (Compactness) *Let $\{V_h\} \subseteq \mathbf{YV}(\Omega, \mathbb{R}^n)$ be a sequence of Young varifolds such that $\sup_h \mu_{V_h}(\Omega) < \infty$. Then, possibly extracting a subsequence, $V_h \xrightarrow{*} V$ with $V \in \mathbf{YV}(\Omega, \mathbb{R}^n)$.*

Proof : By definition of Young varifolds, there exists a sequence of Young measures $\{v_h\}$ such that $V_h = V_{v_h}$ and by the uniform bound on μ_{v_h} we get

$$\sup_h \left[\int_{\Omega} \int_{\mathbb{R}^n} |z| d(v_h)_x(z) dx + \lambda_{v_h}(\overline{\Omega}) \right] < \infty.$$

Then, by Theorem 5.4, there exists a Young measure ν such that $v_h \xrightarrow{Y} \nu$ (possibly extracting a subsequence) and we get

$$\lim_{h \rightarrow \infty} \int_{G_{n-1}(\Omega)} f(x, S) dV_{v_h}(x, S) = \lim_{h \rightarrow \infty} \langle \langle g, v_h \rangle \rangle = \langle \langle g, \nu \rangle \rangle \quad \forall f \in C_c(G_{n-1}(\Omega)) \quad (9)$$

where $g(x, z) = |z|f(x, z^\perp)$. Then considering the Young varifold associated with ν , (9) proves that $V_h \xrightarrow{*} V_\nu$ and the proposition ensues. \square

The **first variation of a Young varifold** V_ν is defined as

$$\begin{aligned} \delta V_\nu : X \in C_c(\Omega, \mathbb{R}^n) &\longmapsto \int_{G_{n-1}(\Omega)} \operatorname{div}_S X(x) dV_\nu(x, S) \\ &= \int_{\Omega} \int_{\mathbb{R}^n} |z| \operatorname{div}_{z^\perp} X d\nu_x(z) dx + \int_{\Omega} \int_{\mathbb{S}^{n-1}} \operatorname{div}_{z^\perp} X d\nu_x^\infty(z) d\lambda_\nu. \end{aligned}$$

Example 6.4 If $u \in \operatorname{BV}(\Omega)$ then the Young varifold $V_{v_{Du}}$ associated with the gradient Young measure v_{Du} is defined as:

$$\int_{G_{n-1}(\Omega)} f(x, S) dV_{v_{Du}}(x, S) = \int_{\Omega} |\nabla u| f(x, \nabla u^\perp) dx + \int_{\Omega} f\left(x, \frac{D^s u^\perp}{|D^s u|}\right) d|D^s u|$$

for all $f \in C_c(G_{n-1}(\Omega))$. The weight measure is

$$\mu_{V_\nu} = |Du|$$

and the first variation is

$$\delta V_{v_{Du}}(X) = \int_{\Omega} |\nabla u| \operatorname{div}_{\nabla u^\perp} X dx + \int_{\Omega} \operatorname{div} \frac{D^s u^\perp}{|D^s u|} X d|D^s u|$$

for all $X \in C_c(\Omega, \mathbb{R}^n)$.

We can observe that, if $\{u_h\}$ is bounded in $\operatorname{BV}(\Omega)$, then, by Proposition 5.9, there exists a subsequence (not relabeled) such that $v_{Du_h} \xrightarrow{Y} \nu$ thus $V_{v_{Du_h}} \xrightarrow{*} V_\nu$. Furthermore, if $u_h \rightarrow u$ strictly in BV , Proposition 5.9 implies that $V_{v_{Du_h}} \xrightarrow{*} V_{v_{Du}}$.

Remark 6.5 (Smooth functions) If $u \in C^2(\Omega)$, $\Omega \subset \mathbb{R}^n$, then for all $f \in C_c(G_{n-1}(\Omega))$ we get

$$\int_{G_{n-1}(\Omega)} f(x, z) dV_{v_{Du}}(x, z) = \int_{\Omega} f(x, \nabla u^\perp) |\nabla u| dx.$$

The weight measure is $\mu_{V_{v_{Du}}}(A) = |Du|(A) = \int_A |\nabla u| dx$, $\forall A \subseteq \Omega$. Moreover, for all $X \in C_c(\Omega, \mathbb{R}^n)$

$$\delta V_{v_{Du}}(X) = \int_{\Omega} |\nabla u| \operatorname{div}_{\nabla u^\perp} X dx.$$

Since ∇u is regular, the coarea formula yields $\delta V_{v_{Du}}(X) = \int_{\mathbb{R}} \int_{\partial\{u>t\} \cap \Omega} \operatorname{div}_{\partial\{u>t\}} X \, d\mathcal{H}^{n-1} \, dt$ because $\nabla u^\perp(x)$ is the tangent space at x to the isolevel surface $\{y, u(y) = u(x)\}$. Moreover, for a.e. $t \in \mathbb{R}$ the generalized mean curvature of the varifold $V_t = \mathbf{v}(\partial\{u > t\}, 1)$ coincides with the mean curvature vector of the C^2 $(n-1)$ -manifold $\partial\{u > t\}$.

Now, a normal unit vector to $\partial\{u > t\}$ at $x \in \partial\{u > t\}$ is $\nabla u(x)/|\nabla u(x)|$ and, denoting by $\mathbf{H}_t(x)$ the mean curvature (in the manifold sense !) of $\partial\{u > t\}$ at x , we get

$$\mathbf{H}_t(x) = -(\operatorname{div} \frac{\nabla u}{|\nabla u|}(x)) \frac{\nabla u}{|\nabla u|}(x).$$

Then, using the representation formula for the first variation of rectifiable varifolds and the coarea formula, it follows that

$$\delta V_{v_{Du}}(X) = - \int_{\mathbb{R}} \int_{\partial\{u>t\} \cap \Omega} \langle X, \mathbf{H}_t \rangle \, d\mathcal{H}^{n-1} \, dt = \int_{\Omega} |\nabla u| \langle X, (\operatorname{div} \frac{\nabla u}{|\nabla u|}) \frac{\nabla u}{|\nabla u|} \rangle \, dx.$$

Then the mean curvature vector of the varifold $V_{v_{Du}}$ is given by

$$\mathbf{H}_{V_{v_{Du}}}(x) = - \frac{\delta V_{v_{Du}}}{\mu_{V_{v_{Du}}}}(x) = \mathbf{H}_t(x) = -(\operatorname{div} \frac{\nabla u}{|\nabla u|}) \frac{\nabla u}{|\nabla u|}(x) \quad \mathcal{L}^n - a.e \text{ in } \Omega.$$

Thus, for all $p > 1$, $F(u, \Omega) = \int_{\Omega} |\nabla u| \left(1 + \left| \operatorname{div} \frac{\nabla u}{|\nabla u|} \right|^p \right) \, dx = \int_{\Omega} \left[1 + \left| \mathbf{H}_{V_{v_{Du}}}(x) \right|^p \right] \, d\mu_{V_{v_{Du}}}.$

This formula shows the relationship, in the case of a regular function, between the generalized Willmore functional and the Young varifold associated with the Young measure v_{Du} and it motivated our interest for the Willmore functional for Young varifolds studied in the next section.

7 The Willmore functional for Young varifolds

In this section we extend the Willmore functional to Young varifolds. We consider the class

$$\mathbf{GY}(u) = \{v \in \mathbf{GY}(\Omega, \mathbb{R}^n) : \operatorname{Bar}_v \llcorner \Omega = Du\}.$$

Proposition 7.1 *The set $\mathbf{GY}(u)$ is weakly* closed (as a subset of $(\mathbf{E}(\Omega, \mathbb{R}^n))^*$).*

Proof : Take v from the weak closure of $\mathbf{GY}(u)$. By Theorem 5.3, $v \in \mathbf{Y}(\Omega, \mathbb{R}^n)$ and there exists a sequence $\{v_h\} \subset \mathbf{GY}(u)$ such that, for every $h \in \mathbb{N}$ and for every $f \in \mathbf{E}(\Omega, \mathbb{R}^n)$,

$$|\langle \langle v_h, f(x, z) \rangle \rangle - \langle \langle v, f(x, z) \rangle \rangle| \leq \frac{1}{h} \quad \text{and} \quad |\langle \langle v_h, |z| \rangle \rangle - \langle \langle v, |z| \rangle \rangle| \leq \frac{1}{h}.$$

Now, for every h $v_h \in \mathbf{GY}(u)$, and since $W^{1,1}$ -functions are dense in BV with respect to the strict convergence, it follows from Proposition 5.9 that for every $h \in \mathbb{N}$ there exists $u_h \in W^{1,1}(\Omega)$ with

$$\|u_h - u\|_{BV} \leq 1/h$$

and such that $|\int_{\Omega} f(x, \nabla u_h) dx - \langle \langle v_h, f(x, z) \rangle \rangle| \leq \frac{1}{h}$ and $|\|\nabla u_h\|_{L^1} - \langle \langle v_h, |z| \rangle \rangle| \leq \frac{1}{h}$. Being $\{u_h\}$ uniformly bounded in BV(Ω), there exists a subsequence (not relabeled) such that $u_h \overset{*}{\rightharpoonup} u$ in BV and $v_{Du_h} \overset{Y}{\rightharpoonup} \mu \in \mathbf{GY}(\Omega, \mathbb{R}^n)$. Now, the two estimates above show that necessarily $\mu = v$ and we get $\operatorname{Bar}_v \llcorner \Omega = \operatorname{Bar}_{\mu} \llcorner \Omega = Du$, hence $v \in \mathbf{GY}(u)$. \square

We can now define a class of Young varifolds that is suitable in the Willmore context.

Definition 7.2 *The class $\mathbb{V}(u)$ of Young varifolds associated with $v \in \mathbf{GY}(u)$ is defined as*

$$\mathbb{V}(u) = \{V_v \in \mathbf{YV}(\Omega, \mathbb{R}^n) : v \in \mathbf{GY}(u), \|\delta V_v\| \ll \mu_{V_v}\}.$$

The following theorem shows a property of the weight measures of Young varifolds that are associated with Young measures belonging to $\mathbf{GY}(u)$.

Proposition 7.3 *For all $V \in \mathbb{V}(u)$, $\mu_{V_v}(\Omega) \geq |Du|(\Omega)$.*

Proof : For every $v \in \mathbf{GY}(u)$, $\text{Bar}_v \llcorner \Omega = Du$ and, using the Radon-Nikodym decomposition (6),

$$\mu_{V_v}(\Omega) = \int_{\Omega} \int_{\mathbb{R}^n} |z| d\nu_x(z) dx + \lambda_v(\overline{\Omega}) \geq \int_{\Omega} \left[\int_{\mathbb{R}^n} |z| d\nu_x(z) + \frac{\lambda_v}{\mathcal{L}^n}(x) \right] dx + \lambda_v^s(\Omega)$$

Then, using (7), and reminding that ν_x^∞ is a probability measure, it follows that

$$\begin{aligned} \mu_{V_v}(A) &\geq \int_A \left| \int_{\mathbb{R}^n} z d\nu_x + \frac{\lambda_v}{\mathcal{L}^n}(x) \int_{\mathbb{S}^{n-1}} z d\nu_x^\infty \right| dx + \int_A \left| \int_{\mathbb{S}^{n-1}} z d\nu_x^\infty \right| \lambda_v^s \\ &\geq \left| \int_A \int_{\mathbb{R}^n} z d\nu_x dx + \int_A \int_{\mathbb{S}^{n-1}} z d\nu_x^\infty d\lambda_v \right| = |Du(A)| \end{aligned}$$

for every $A \subseteq \Omega$. From the definition of total variation (see [3]: Definition 1.4), we get

$$\mu_{V_v}(\Omega) \geq |Du|(\Omega).$$

□

Remark that, since every $u \in \text{BV}(\Omega)$ can be approximated by a sequence $\{u_h\} \subset \text{W}^{1,1}(\Omega)$ strictly converging to u in BV , Proposition 5.9 implies that $v_{Du} \in \mathbf{GY}(u)$ for all $u \in \text{BV}(\Omega)$.

However $V_{v_{Du}} \notin \mathbb{V}(u)$ in general (see Example 7.4) because it depends on the absolute continuity of $\|\delta \mu_{V_{Du}}\|$ with respect to $\mu_{V_{Du}}$.

Example 7.4 (A case where $V_{v_{Du}} \notin \mathbb{V}(u)$) We consider $E \subset \mathbb{R}^2$ like in Fig. 6, Ω an open set such that $E \subset\subset \Omega$ and $u = \mathbb{1}_E$.

Figure 6: $\delta V_{v_{Du}}$ has a singular component

Remark that $V_{v_{Du}} = \mathbf{v}(\partial E, 1)$ and $\mu_{V_{v_{Du}}} = |D^s u|$. Nevertheless, using the theory of rectifiable varifolds, it is easy to check that $\|\delta V_{v_{Du}}\|$ is not absolutely continuous with respect to $\mu_{V_{v_{Du}}}$. In particular, denoting by σ the generalized boundary measure of $V_{v_{Du}}$, we have $\sigma = 2\mathbf{n}\delta_p$ where \mathbf{n} is the unit vector drawn in Fig. 6.

The mean curvature vector and the Willmore functional associated with a Young varifold are defined as follows

Definition 7.5 (Mean curvature of a Young varifold) *The generalized mean curvature vector of $V \in \mathbb{V}(u)$ is defined as the Radon-Nikodym derivative*

$$\mathbf{H}_V = -\frac{\delta V}{\mu_V}$$

Definition 7.6 (Willmore energy of a Young varifold) *The Willmore energy of a Young varifold is defined as:*

$$W : \mathbb{V}(u) \longrightarrow \mathbb{R}$$

$$W(V) = \int_{\Omega} (1 + |\mathbf{H}_V|^p) d\mu_V \quad p > 1.$$

Remark that in general the class $\mathbb{V}(u)$ is not closed with respect to varifold convergence because, given a sequence (V_h) in $\mathbb{V}(u)$, the condition $\|\delta V_h\| \ll \mu_{V_h}$ may not be preserved in the limit. A sufficient condition that ensures the preservation is a uniform bound (see Proposition 3.2)

$$\sup_h \int_{\Omega} |\mathbf{H}_{V_h}|^p d\mu_{V_h} < +\infty.$$

Remark 7.7 (Regular case) If $u \in C^2(\Omega)$ and $F(u, \Omega) < \infty$ then $v_{Du} \in \mathbf{GY}(u)$ and from Example 6.5 we have $\|\delta V_{v_{Du}}\| \ll \mu_{v_{Du}}$. Then $V_{v_{Du}} \in \mathbb{V}(u)$ and $W(V_{v_{Du}}) = F(u, \Omega) = \bar{F}(u, \Omega)$. Moreover, by the coarea formula,

$$\int_{G_{n-1}(\Omega)} f(x, S) dV_{v_{Du}}(x, S) = \int_{\mathbb{R}} \int_{G_{n-1}(\Omega)} f(x, S) d\mathbf{v}(\partial\{u > t\}, 1) dt$$

so, in the regular case, the Young varifold $V_{v_{Du}}$ satisfies a slicing formula that involves the unit-density varifolds supported on the boundaries of the level sets of u .

We will now illustrate with the examples of Section 5.3 a few situations where we can explicitly calculate the Willmore functional for Young varifolds and we will even show the continuity of the energy for the provided approximating sequences. These examples illustrate that Young varifolds are suitable for catching the limit energy.

Example 7.8 Take the sequence of Young measures studied in Example 5.11 and observe that, for all h , $\mu_{V_h} = \mu_V = \mathcal{L}^2 \llcorner B(0, 1)$. An easy calculation shows that for every h , $\mathbf{H}_{V_h}(x) = \mathbf{H}_V(x) = \frac{x}{|x|^2}$, $\forall x \in B(0, 1)$, and for $p \in (1, 2)$,

$$W(V_{v_h}) = W(V_V) = \int_{B(0,1)} \left(1 + \frac{1}{|x|^p}\right) dx.$$

Example 7.9 Take now the sequence of Young measures studied in Example 5.12. The limit varifold satisfies $\mu_V = 4\mathcal{H}^1(\partial B(0, 1)) = 8\pi$ and $\delta V_V(X) = -4 \int_{\partial B(0,1)} \langle X, x \rangle d\mathcal{H}^1$, therefore $\mathbf{H}_V(x) = x$, $\forall x \in \partial B(0, 1)$, and $W(V_V) = 16\pi$.

For every V_{v_h} , $\mu_{V_{v_h}} = h\mathcal{L}^2(\Omega_h) + \mathcal{H}^1(\partial\Omega_h) = 8\pi$, where $\Omega_h = B(0, 1 + \frac{1}{h}) \setminus B(0, 1 - \frac{1}{h})$ and it arises from an easy calculation that

$$W(V_{v_h}) = 8\pi + 2\pi h \int_{1-1/h}^{1+1/h} \frac{1}{r^{p-1}} dr + 2\pi \left[\left(\frac{h}{h+1}\right)^{p-1} + \left(\frac{h}{h-1}\right)^{p-1} \right]$$

By Lebesgue's Theorem we get $W(V_{v_h}) \rightarrow 8\pi + 4\pi + 4\pi = W(V_v)$.

Example 7.10 Lastly, consider the sequence of Young measures studied in Example 5.13.

For the Young varifold associated with v we have $\mu_{V_v} = \mathcal{L}^2 \llcorner \Omega$ and $\delta V_v(X) = \int_{B(0,1)} \operatorname{div} \frac{x}{|x|} \perp X \, dx$.

An application of the coarea formula yields $\delta V_{v_h}(X) = - \int_{B(0,1)} \langle X, \frac{x}{|x|^2} \rangle \, dx$, therefore $\mathbf{H}_{V_v}(x) = \frac{x}{|x|^2} \forall x \in B(0,1)$, and $W(V_v) = \pi + \int_{B(0,1)} \frac{dx}{|x|^p} = \frac{4-p}{2-p} \pi$. Moreover,

$$W(V_{v_h}) = \pi \sum_{k=0}^{h-1} \frac{2kh+1}{h^3} + 2\pi \sum_{k=0}^{h-1} h \int_{\frac{k}{h}}^{\frac{k+1}{h}} \frac{dr}{r^{p-1}} \rightarrow \pi + 2\pi \int_0^1 \frac{dr}{r^{p-1}} = \frac{4-p}{2-p} \pi,$$

therefore $W(V_{v_h}) \rightarrow \frac{4-p}{2-p} \pi = W(V_v)$.

Remark 7.11 Remark that, in all these examples, we have convergence of the Willmore energy, but the limit varifold is not the varifold associated with Du , i.e. $V_v \neq V_{v_{Du}}$. In fact the sequence $\{u_h\}$ converges to $u = 0$ weakly* in BV but v_{Du_h} does not converge (in the sense of Young measures) to the gradient Young measure associated with 0. For instance, in Example 7.10, the sequence of gradients creates some curvature at the limit that is captured by the diffuse part λ_v .

Moreover, since u is identically 0, its level sets are empty for all positive levels but $\mu_{V_v} \neq 0$. This means that the level lines of u do not provide any information about the Young measure generated by $\{u_h\}$ so it will not be possible in general to write a slicing formula (like in Remark 7.7) that links the measures belonging to $\mathbf{GY}(u)$ and the level sets of u .

8 Relaxation of the generalized Willmore functional and Young varifolds

This section is devoted to the minimum problem associated with the Willmore functional for Young varifolds and its relationship with the relaxation problem for F . In the remaining, Ω is an open, bounded Lipschitz domain.

Theorem 8.1 *Let $u \in \mathbf{BV}(\Omega)$ with $\bar{F}(u, \Omega) < \infty$. Then*

1. $\mathbb{V}(u) \neq \emptyset$
2. *The problem $\operatorname{Min} \{W(V) : V \in \mathbb{V}(u)\}$ has a solution,*
3. $\bar{F}(u, \Omega) \geq \operatorname{Min}\{W(V) : V \in \mathbb{V}(u)\}$.

Proof : Let $\{u_h\} \subset C^2(\Omega)$ be a sequence converging to u in $L^1(\Omega)$ and such that $\bar{F}(u, \Omega) = \lim_{h \rightarrow \infty} F(u_h, \Omega)$. We can also suppose that $F(u_h, \Omega)$ is uniformly bounded so, possibly taking a subsequence, $u_h \overset{*}{\rightharpoonup} u$ in $\mathbf{BV}(\Omega)$. Then, by Remark 6.5, the Young varifolds $V_{v_{Du_h}}$ associated with the gradient Young measures v_{Du_h} satisfy

$$F(u_h, \Omega) = W(V_{v_{Du_h}}), \quad \forall h.$$

Moreover, by Proposition 5.9 and possibly taking a subsequence, we can assume that $v_{D_{u_h}} \xrightarrow{Y} \tilde{v} \in \mathbf{GY}(\Omega, \mathbb{R}^n)$ and hence $V_{v_{D_{u_h}}} \xrightarrow{*} V_{\tilde{v}}$. Clearly, as $u_h \xrightarrow{*} u$ in $BV(\Omega)$, we have $\text{Bar}_{\tilde{v}} \llcorner \Omega = Du$ which implies that $\tilde{v} \in \mathbf{GY}(u)$.

Then, we deduce from Proposition 3.2 that $\|\delta V_{\tilde{v}}\| \ll \mu_{V_{\tilde{v}}}$ and

$$W(V_{\tilde{v}}) \leq \liminf_{h \rightarrow \infty} W(V_{v_{D_{u_h}}}),$$

Therefore $V_{\tilde{v}} \in \mathbb{V}(u)$ and,

$$\bar{F}(u, \Omega) \geq \inf\{W(V) : V \in \mathbb{V}(u)\} \quad (10)$$

Let $\{V_h\} \subset \mathbb{V}(u)$ be a minimizing sequence such that $W(V_h)$ is uniformly bounded, therefore $\{\mu_{V_h}(\Omega)\}$ is uniformly bounded. By Theorem 5.4 and Proposition 7.1, there exists $v \in \mathbf{GY}(u)$ such that (possibly extracting a subsequence) $v_h \xrightarrow{Y} v$ and, by Proposition 6.2, $V_h \xrightarrow{*} V_v$.

Moreover, by Proposition 3.2, $\|\delta V_v\| \ll \mu_{V_v}$, $V_v \in \mathbb{V}(u)$ and

$$W(V_v) \leq \liminf_{n \rightarrow \infty} W(V_h)$$

which proves that

$$W(V_v) = \text{Min}\{W(V) : V \in \mathbb{V}(u)\}.$$

Lastly, 3. follows from (10). □

As a by-product of the previous proof we have the

Corollary 8.2 *For all $A > 0$, the set $\mathbb{V}_A(u) = \{V \in \mathbb{V}(u), W(V) \leq A\}$ is sequentially compact, and W is lower semicontinuous on it.*

Remark 8.3 Three questions arise naturally from Theorem 8.1:

Q.1 Does the equality hold in Theorem 8.1, 3. ?

Q.2 If not, what additional assumption should be taken to guarantee it ?

Q.3 Can we at least always find $V \in \mathbb{V}(u)$ such that $\bar{F}(u, \Omega) = W(V_v)$?

The answer to the first question is *negative*:

Proposition 8.4 *There exists $u \in BV(\Omega)$ such that $\bar{F}(u, \Omega) < \infty$ and*

$$\bar{F}(u, \Omega) > \text{Min}\{W(V) : V \in \mathbb{V}(u)\}.$$

Proof : The counterexample is the function $u = \mathbb{1}_E$ shown in Figure 7, left. The middle figure shows the limit configuration obtained with a smooth sequence (u_h) converging weakly to $\mathbb{1}_E$ in BV and such that $\sup_h F(u_h) < +\infty$. If the assumption $\sup_h F(u_h) < +\infty$ is dropped then the right configuration can be obtained with a suitable smooth sequence (w_h) (just taking the previous situation and allowing the creation of a double right angle at the center). Associating w_h with a Young measure ν_h , and passing to the limit as Young measures, yields a limit Young measure ν whose support is the topological boundary of the right figure. An easy calculus shows that the associated Young varifold V_ν has no curvature at the center, therefore the central cross has no energy, thus $W(V_\nu) < \bar{F}(\mathbb{1}_E)$.

Interestingly, the same counterexample can be used to show that the functionals

$$\frac{1}{2c_0} \int_{\mathbb{R}^n} \left(\varepsilon |\nabla u_\varepsilon|^2 + \frac{1}{\varepsilon} \Psi(u_\varepsilon) \right) dx + \frac{1}{4c_0 \varepsilon} \int_{\mathbb{R}^n} \left(2\varepsilon \Delta u_\varepsilon - \frac{1}{\varepsilon} \Psi'(u_\varepsilon) \right)^2 dx,$$

Figure 7: Left : a set E . Middle: a limit configuration showing that $\bar{F}(\mathbb{1}_E) < \infty$. Right: this configuration shows the support of a Young varifold $V \in \mathbb{V}(\mathbb{1}_E)$ such that $W(V) < \bar{F}(\mathbb{1}_E)$.

(where $\Psi(s) = (1 - s^2)^2$ and $c_0 = \int_{-1}^1 \sqrt{\Psi(t)} dt$) do not Γ -converge to $\bar{F}(\mathbb{1}_E)$ as $\varepsilon \rightarrow 0$ (but the Γ -convergence holds in dimensions 2 and 3 when E is smooth). The reason why such singular structure can be obtained is due to the existence of solutions of the Allen-Cahn equation with singular nodal set.

Clearly, the class of Young varifolds is richer than what is strictly needed to ensure the equality in Theorem 8.1, 3. An even more extreme example is provided by the set E in Figure 8 below: it follows from the results in [7] that $\bar{F}(\mathbb{1}_E) = +\infty$ (because there are oddly many cusps), yet $\mathbb{1}_E$ can be approximated by a sequence of smooth functions with uniformly bounded BV norm, and the associated Young varifolds converge to a limit Young varifold V_v whose energy near the triple point is null because it has no singular part and null curvature (being the three angles equal, the singularities compensate). It follows that $W(V_v) < +\infty$. Again, the framework of Young varifolds is suitable for catching the limit configuration. \square

Figure 8: A set E such that $\bar{F}(\mathbb{1}_E) = \infty$ but that can be associated with a Young varifold having finite energy.

Being the answer to question Q.1 negative, what about Q.2? To avoid the singular situations of Figures 7, 8, it is enough to restrict the class of Young varifolds to those that can be approximated by sequences of smooth functions uniformly controlled in energy, i.e. working with the class

$$\mathbb{V}_B(u) = \{V_v \in \mathbf{YV}(\Omega, \mathbb{R}^n) : v \in \mathbf{GY}(u), \|\delta V_v\| \ll \mu_{V_v}, \exists (u_h) \xrightarrow{*} u \text{ in BV}, F(u_h) \leq B\}.$$

We do not know however if using such restriction is enough to guarantee the equality in Theorem 8.1, 3. To study in [9] the representation by varifolds in dimension 2 of the relaxed elastica functional, Bellettini and Mugnai need varifolds having a unique tangent line at every point. In our context and for our more general functional, one can reasonably

think that a more intrinsic condition for the equality to hold could also involve tangential conditions, i.e. the existence of tangent planes along the support of λ_ν , together with orthogonality conditions on ν_x^∞ . This is however a completely open problem.

Let us end this (long!) remark with a few words on question Q.3. The answer is **positive** in dimension 2, as stated in Theorem 8.6 below where we use the connection between systems of curves belonging to $\mathcal{A}(u)$ and Young varifolds. In particular, given a system of curves, one can define a Young varifold with a coarea structure similar to the one in Remark 7.7. The proof uses the following theorem on the locality of curvature for integral 1-varifolds.

Theorem 8.5 (Locality of mean curvature, [21], Thm 2.1) *Let $V_1 = \mathbf{v}(M_1, \theta_1)$, $V_2 = \mathbf{v}(M_2, \theta_2)$ be two integral 1-varifolds in \mathbb{R}^n and let $\mathbf{H}_1, \mathbf{H}_2$ be their generalized curvature vectors. Then*

$$\mathbf{H}_1 = \mathbf{H}_2 \quad \mathcal{H}^1\text{-a.e. on } M_1 \cap M_2.$$

Theorem 8.6 (Representation of the relaxation in dimension 2) *Let $u \in \text{SBV}(\mathbb{R}^2)$ with compact support and $\bar{F}(u) < \infty$. Let $\Phi \in \mathcal{A}(u)$ with $G(\Phi) < \infty$ and suppose that there exists a bounded Lipschitz domain Ω such that*

$$\bigcup_{t \in \mathbb{R}} (\Phi(t)) \subset\subset \Omega. \quad (11)$$

Then, there exists a Young measure $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^2)$ such that $V_\nu \in \mathbb{V}(u)$ and

$$G(\Phi) = W(V_\nu).$$

In particular, there exists $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^2)$ such that $V_\nu \in \mathbb{V}(u)$ and

$$\bar{F}(u) = W(V_\nu)$$

Proof : We first remark that, since $\Phi(t)$ is a system of curves of class $W^{2,p}$ for a.e. t , the 1-rectifiable varifold $V_t = \mathbf{v}(\Phi(t), \theta_{\Phi(t)})$ ($\theta_{\Phi(t)}$ is the density of the system $\Phi(t)$, see Definition 2.1) is such that

$$\|\delta V_t\| \ll \mu_{V_t}$$

(see Remark 4.7) so for every $X \in C_c(\Omega, \mathbb{R}^2)$ we have

$$\delta V_t(X) = - \int_{\Omega} \langle X, \mathbf{H}_{V_t} \rangle d\mu_{V_t} \quad (12)$$

where \mathbf{H}_{V_t} is the mean curvature of the varifold $\mathbf{v}(\Phi(t), \theta_{\Phi(t)})$.

Let $\Phi \in \mathcal{A}(u)$ and consider the varifold V , supported on $\bigcup_{t \in \mathbb{R}} (\Phi(t)) \times G(2, 1)$, defined as

$$V(E \times A) = \int_{\mathbb{R}} \mathbf{v}(\Phi(t), \theta_{\Phi(t)})(E \times A) dt, \quad \forall E \times A \subset G_1(\Omega) \quad (13)$$

where $\theta_{\Phi(t)}$ is the density of the system $\Phi(t)$.

Then for every $f \in C_c(G_1(\Omega))$ we get

$$\int_{G_1(\Omega)} f(x, S) dV(x, S) = \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)}(x) f(x, n_t(x)^\perp) d\mathcal{H}^1 dt \quad (14)$$

where $n_t(x)$ denotes a unit normal to the system $\Phi(t)$ at x and $\theta_t(x)$ denotes the density of the system $\Phi(t)$ at x .

By definition of $\mathcal{A}(u)$, for \mathcal{L}^1 -a.e. t ($\Phi(t) \supseteq \partial^*\{u > t\}$ (up to a \mathcal{H}^1 -negligible set) so

$$\begin{aligned} \int_{G_1(\Omega)} f(x, S) dV(x, S) &= \int_{\mathbb{R}} \int_{\partial^*\{u > t\}} f(x, n_t(x)^\perp) d\mathcal{H}^1 dt + \\ &+ \int_{\mathbb{R}} \int_{\partial^*\{u > t\}} (\theta_{\Phi(t)}(x) - 1) f(x, n_t(x)^\perp) d\mathcal{H}^1 dt + \int_{\mathbb{R}} \int_{\Phi(t) \setminus \partial^*\{u > t\}} \theta_{\Phi(t)}(x) f(x, n_t(x)^\perp) d\mathcal{H}^1 dt. \end{aligned} \quad (15)$$

The coarea formula in BV yields that

$$\int_{\mathbb{R}} \int_{\partial^*\{u > t\}} f(x, n_t(x)^\perp) d\mathcal{H}^1 dt = \int_{\mathbb{R}^2} f(x, Du(x)^\perp) d|Du|. \quad (16)$$

The decomposition theorem for the derivative of SBV functions implies

$$|Du| = |\nabla u| \mathcal{L}^2 + |D^s u|$$

where ∇u is the approximate gradient of u and $|D^s u| = |u^+ - u^-| \mathcal{H}^1 \llcorner J_u$ where J_u is the set of approximate jump points of u , so

$$\int_{\mathbb{R}^2} f(x, Du(x)^\perp) d|Du| = \int_{\mathbb{R}^2} |\nabla u|(x) f(x, \nabla u(x)^\perp) dx + \int_{\Omega} f(x, D^s u(x)^\perp) d|D^s u|. \quad (17)$$

Moreover we can consider the measure m defined as:

$$m(A) = \int_{\mathbb{R}} \int_{[\Phi(t) \setminus \partial^*\{u > t\}] \cap A} \theta_{\Phi(t)}(x) d\mathcal{H}^1 dt + \int_{\mathbb{R}} \int_{\partial^*\{u > t\} \cap A} (\theta_{\Phi(t)}(x) - 1) d\mathcal{H}^1 dt \quad (18)$$

for every measurable set $A \subset \Omega$ and, from (11), we get

$$m(\partial\Omega) = 0 \quad (19)$$

Thus, by (15), (16), (17) and (18), we can write

$$\begin{aligned} \int_{G_1(\Omega)} f(x, S) dV(x, S) &= \int_{\Omega} |\nabla u|(x) f(x, \nabla u(x)^\perp) dx + \int_{\Omega} f(x, D^s u(x)^\perp) d|D^s u| \\ &+ \int_{\Omega} f(x, n_t(x)^\perp) dm(x). \end{aligned} \quad (20)$$

We deduce from the previous equality that V is a Young varifold. In fact, by (20), we get

$$\int_{G_1(\Omega)} f(x, S) dV(x, S) = \langle \langle \nu, |z| f(x, z^\perp) \rangle \rangle \quad (21)$$

where $\nu = (\nu_x, \nu_x^\infty, \lambda_\nu)$ is the Young measure defined as:

$$\nu_x = \delta_{\nabla u(x)}, \quad \lambda_\nu = |D^s u| + m, \quad \nu_x^\infty = \begin{cases} \delta_{\frac{D^s u}{|D^s u|}(x)} & \text{if } x \in J_u \\ \frac{1}{2} (\delta_{n_t(x)} + \delta_{-n_t(x)}) & \text{if } x \in \text{spt } m \end{cases} \quad (22)$$

where $n_t(x)$ is a unit normal vector to the system $\Phi(t)$ at x . Remark that, as different curves belonging either to the same system or to different systems may intersect only tangentially, the previous measure is well defined.

By (11) and (19) we have $\lambda_\nu(\partial\Omega) = 0$ and in addition

$$\int_{\Omega} \int_{\mathbb{R}^n} |z| d\nu_x(z) dx + \lambda_\nu(\overline{\Omega}) = \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)} d\mathcal{H}^1 dt \leq G(\Phi) < \infty$$

so, using Theorem 5.10, we get $\nu \in \mathbf{GY}(\Omega, \mathbb{R}^2)$. In addition it is easy to check that $\text{Bar}_\nu = Du$ so $\nu \in \mathbf{GY}(u)$. To end the proof we have to show that $V = V_\nu \in \mathbb{V}(u)$ and

$$W(V) = \int_{\mathbb{R}} W(\Phi(t)) dt = G(\Phi).$$

For every measurable set A ,

$$\mu_V(A) = \int_{\mathbb{R}} \int_{\Phi(t) \cap A} \theta_{\Phi(t)} d\mathcal{H}^1 dt$$

and for every $X \in C_0^1(\Omega, \mathbb{R}^2)$, by (14) and (12), we get

$$\delta V(X) = \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)} \text{div}_{\Phi(t)} X d\mathcal{H}^1 dt = - \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)} \langle X, \mathbf{H}_{V_t} \rangle d\mathcal{H}^1 dt = - \int_{\Omega} \langle X, \mathbf{H} \rangle d\mu_V$$

where the last equality follows from the locality of the mean curvature (see Theorem 8.5), that guarantees, together with the properties of Φ , that the mean curvature is uniquely defined μ_V -almost everywhere, .

It follows from the expression of the first variation that $\mathbf{H}_V = \mathbf{H}$, thus $\|\delta V\| \ll \mu_V$ so $V = V_\nu \in \mathbb{V}(u)$. Moreover, by the coarea formula,

$$\begin{aligned} G(\Phi) &= \int_{\mathbb{R}} W(\Phi(t)) dt = \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)} d\mathcal{H}^1 dt + \int_{\mathbb{R}} \int_{\Phi(t)} \theta_{\Phi(t)} |\mathbf{H}_{V_t}|^p d\mathcal{H}^1 dt \\ &= \mu_V(\Omega) + \int_{\Omega} |\mathbf{H}_V|^p d\mu_V = W(V). \end{aligned}$$

□

Remark 8.7 Does a similar result hold in higher dimension ? This is also an open problem. Generalizing to higher dimension the strategy used in dimension 2 is very delicate because we do not have any description by parametric foliation of our limit functions, see the discussion in the introduction. We believe instead that the Young varifold structure is rich enough and keeps track of sufficiently many information in the limit to allow a desingularization procedure that is necessary to get the representation of the limit Willmore energy using Young varifolds. This is the purpose of ongoing research and we conclude this discussion with a conjecture.

Conjecture 8.8 For every $u \in \text{BV}(\Omega)$ with $\bar{F}(u) < \infty$, there exists $V \in \mathbb{V}(u)$ such that

$$\bar{F}(u) = W(V).$$

The set $\mathbf{GY}(0)$ plays an important role in [20], and it is also of interest in our context.

Definition 8.9 Given $u \in \text{BV}(\Omega)$, $\Omega \subset \mathbb{R}^n$, we denote by $\nu_{Du} + \mathbf{GY}(0)$ the class of gradient Young measures that decomposes into $\nu_{Du} + \tilde{\nu}$ for some $\tilde{\nu} \in \mathbf{GY}(0)$.

It is easy to check that $\nu_{Du} + \mathbf{GY}(0) \subseteq \mathbf{GY}(u)$. Remark that if $\nu \in \nu_{Du} + \mathbf{GY}(0)$ then

$$V_\nu = V_{\nu_{Du}} + V_{\tilde{\nu}}, \quad \text{with } \tilde{\nu} \in \mathbf{GY}(0).$$

Proposition 8.10 The Young measure ν defined in (22) belongs to $\nu_{Du} + \mathbf{GY}(0)$.

Proof : For every $f \in \mathbf{E}(\Omega; \mathbb{R}^2)$ we have

$$\begin{aligned} \langle \langle v, f \rangle \rangle &= \int_{\Omega} f(x, \nabla u(x)) \, dx + \int_{\Omega} f^{\infty} \left(x, \frac{D^s u}{|D^s u|} \right) d|D^s u| + \int_{\Omega} f^{\infty}(x, n(x)) \, dm = \\ &= \langle \langle v_{Du}, f \rangle \rangle + \langle \langle \tilde{v}, f \rangle \rangle \end{aligned}$$

where \tilde{v} is defined by the following triplet:

$$\tilde{v}_x = \delta_0, \quad \lambda_{\tilde{v}} = m, \quad \tilde{v}_x^{\infty} = \frac{1}{2} (\delta_{n(x)} + \delta_{-n(x)}). \quad (23)$$

Then $v = v_{Du} + \tilde{v}$ and it is sufficient to prove that $\tilde{v} \in \mathbf{GY}(0)$. Now, $m(\Omega) < \infty$ and $m(\partial\Omega) = 0$ so, by Theorem 5.10, $\tilde{v} \in \mathbf{GY}(\Omega, \mathbb{R}^2)$. Moreover $\text{Bar}_{\tilde{v}} = 0$ thus $\tilde{v} \in \mathbf{GY}(0)$. \square

Definition 8.11 We denote by $\mathbb{V}_0(u)$ the class of Young varifolds $V_v \in \mathbb{V}(u)$ such that $v \in v_{Du} + \mathbf{GY}(0)$, thus for every $V \in \mathbb{V}_0(u)$

$$V = V_{v_{Du}} + V_{\tilde{v}}, \quad \text{with } \tilde{v} \in \mathbf{GY}(0).$$

Remark 8.12 The definition of $\mathbb{V}_0(u)$ is motivated by the relationship between a general $v \in \mathbf{GY}(u)$ and v_{Du} . Remark 6.5 shows that v_{Du} represents $\bar{F}(u)$ for every $u \in C^2(\Omega)$ and we have

$$\bar{F}(u) = W(v_{Du}).$$

However, Remark 7.4 implies that we cannot expect such a relation for every $u \in \text{BV}(\Omega)$ because in general $V_{v_{Du}} \notin \mathbb{V}(u)$. Thus, a natural question is the following: given $u \in \text{BV}(\Omega)$, how different are the measures $v \in \mathbf{GY}(u)$ and v_{Du} ?

This leads to characterizing the measures belonging to $\mathbb{V}_0(u)$ in order to estimate \tilde{v} . Several questions arise naturally. Do $\mathbb{V}_0(u)$ and $\mathbb{V}(u)$ coincide? Does the solution of the minimum problem in Proposition 8.1 live in $\mathbb{V}_0(u)$? This would mean that, in order to reach the minimum of W , one should take an “economic” \tilde{v} , which is very expectable. But, so far, all these questions remain open.

Let us examine what can be said about the minimization of W in $\mathbb{V}_0(u)$.

Theorem 8.13 Let $u \in \text{BV}(\Omega)$, $\Omega \subset \mathbb{R}^n$, such that $\bar{F}(u, \Omega) < \infty$. If there exists $V \in \mathbb{V}_0(u)$ such that $W(V) < \infty$ then the problem

$$\text{Min} \{W(V) : V \in \mathbb{V}_0(u)\}$$

has at least one solution.

Proof : Let $\{V_h\} \subset \mathbb{V}_0(u)$ be a minimizing sequence. By definition of $\mathbb{V}_0(u)$ we can take a sequence $\{\tilde{v}_h\} \subset \mathbf{GY}(0)$ such that

$$V_h = V_{v_{Du}} + V_{\tilde{v}_h} \quad \forall h.$$

We can suppose $W(V_h)$ uniformly bounded so we get

$$\sup_h \mu_{V_{\tilde{v}_h}}(\Omega) < \infty.$$

Then, by Theorems 5.4 and 7.1, there exist a subsequence (not relabeled) of $\{\tilde{v}_h\}$ and a Young measure $\tilde{v} \in \mathbf{GY}(0)$ such that

$$\tilde{v}_h \xrightarrow{\mathbf{Y}} \tilde{v}.$$

Then we get $v_h = v_{Du} + \tilde{v}_h \xrightarrow{Y} v = v_{Du} + \tilde{v}$ and $V_h \xrightarrow{*} V_v$, where $V_v = V_{v_{Du}} + V_{\tilde{v}}$ is the Young varifold associated with the gradient Young measure $v = v_{Du} + \tilde{v}$, $\tilde{v} \in \mathbf{GY}(0)$.

In addition, by Proposition 3.2, we have $\|\delta V_v\| \ll \mu_{V_v}$ and $W(V_v) \leq \liminf_{n \rightarrow \infty} W(V_h)$. Then $V_v \in \mathbb{V}_0(u)$ and $W(V_v) = \text{Min} \{W(V) : V \in \mathbb{V}_0(u)\}$, and the theorem ensues. \square

The next corollary, that follows from Theorem 8.6, points out the relationship in dimension 2 between Young varifolds in $\mathbb{V}_0(u)$ and the relaxation problem on a bounded domain.

Corollary 8.14 *Let $u \in \text{SBV}(\mathbb{R}^2)$ with compact support and such that $\bar{F}(u, \mathbb{R}^2) < \infty$. There exists a bounded open domain Ω and a Young measure $v \in \mathbf{GY}(\Omega, \mathbb{R}^2)$ such that $V_v \in \mathbb{V}_0(u)$ and*

$$\bar{F}(u, \mathbb{R}^2) = \inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\} = W(V_v).$$

Proof: By Theorem 2.7 there exists $\Phi \in \mathcal{A}(u)$ such that $\bar{F}(u, \mathbb{R}^2) = G(\Phi)$ and, by Proposition 2.8, there exists an open bounded domain Ω with

$$\bigcup_{t \in \mathbb{R}} (\Phi(t)) \subset \subset \Omega$$

and such that $u \in \text{BV}(\Omega)$ and

$$\inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\} = \bar{F}(u, \mathbb{R}^2) = G(\Phi)$$

Then, using Theorem 8.6, we can define a suitable Young measure $v \in \mathbf{GY}(\Omega, \mathbb{R}^2)$ such that $V_v \in \mathbb{V}(u)$ and

$$\inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\} = G(\Phi) = W(V_v).$$

Moreover, by Proposition 8.10, $V_v \in \mathbb{V}_0(u)$ and, by Theorem 8.13, we have

$$\text{Min}\{W(V) : V \in \mathbb{V}_0(u)\} \leq \inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\}.$$

\square

Remark 8.15 In the previous corollary, the quantity

$$\inf \left\{ \liminf_{h \rightarrow \infty} F(u_h, \Omega) : \{u_h\} \in C_c^2(\Omega), u_h \xrightarrow{L^1(\Omega)} u \right\}$$

corresponds to the relaxation of F using approximating functions in C_c^2 instead of C^2 . This definition is well posed but induces different properties for the relaxed functional, as discussed in [24] where some examples are also provided. We shall adopt this definition over this remark to show the link between Young varifolds, Young measures and the Willmore functional.

In the regular planar case (i.e. $u \in C_c^2(\Omega)$, $\Omega \subset \mathbb{R}^2$) there are two natural frameworks to represent \bar{F} :

- by a coarea-type formula, using the representation by systems of curves of class $W^{2,p}$:

$$\bar{F}(u, \Omega) = G(\Phi[u]) \quad \forall u \in C_c^2(\Omega);$$

- by the varifold theory (see Remark 6.5), using Young varifolds:

$$\bar{F}(u, \Omega) = W(V_{v_{Du}}) \quad \forall u \in C_c^2(\Omega).$$

Theorem 8.6 and Corollary 8.14 state that, as in the regular case, Young varifolds provide a natural framework to represent \bar{F} , at least in dimension 2. Moreover, the definition of the Young measure v in (22) shows the relationship between the Young varifold representing $\bar{F}(u, \Omega)$ and $V_{v_{Du}}$: the Young varifold involves an additional term that contains in particular all "ghost" parts, as in Figure 2.

9 Conclusion

We introduced in this paper a new framework to address the relaxation of a generalized Willmore functional. We believe that this combination of Young measures and varifolds is the right approach to track, in the limit of oscillations and concentration, the behavior of the energy. In addition, this framework has a major advantage over representations by foliation: the compactness and the semicontinuity of the energy (under some constraints) come easily, as shown in Corollary 8.2

We showed in the paper several properties of Young varifolds, we proved a representation result for \bar{F} in dimension 2 (Theorem 8.6, Corollary 8.14), and, in any dimension ≥ 2 , we proved an inequality that involves a minimum problem for Young varifolds with prescribed barycenter (Theorem 8.1).

There are several obstacles to get a full understanding of the problem:

- The class of Young varifolds associated with a given function is very rich. This is due to the fact that there are infinitely many Young measures that are the limits of sequences of gradient Young measures associated with smooth functions u_h that converge weakly-* to 0 in BV. It is reasonable to think, however, that minimizing W in $\mathbb{V}(u)$ reduces considerably the measures of interest.
- The proof of the representation result in dimension 2 (Theorem 8.6, Corollary 8.14) strongly relies on Theorem 2.7 that involves a curve stretching technique. This technique can hardly be generalized to higher dimensions, in particular because the accurate description of the boundaries of sets with finite relaxed energy is still an open problem. Another strategy, that has been totally unexplored so far, requires understanding how a limit Young varifold can be regularized with a control of the energy, using in particular the directions of concentration indicated by v_x^∞ .

Beyond the relaxation of the generalized Willmore functional, we may think at other problems that could be tackled with Young varifolds, for instance understanding precisely Γ -limits of suitable functionals when the underlying function is unsmooth, or defining accurately the flow associated with the generalized Willmore functional in order to have a new look at the critical points. We believe that the versatility of Young varifolds makes them delicate but powerful tools.

Acknowledgments

We warmly thank Vicent Caselles and Matteo Novaga for the many discussions we had on the relaxation of the Willmore functional before the current work was initiated. We also thank Giovanni Bellettini and Luca Mugnai for our discussions on related phase-field

approximation issues.
