Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

# Modeling environmental data

We are interested in the modelization of environmental data. e.g.

- precipitation,
- temperature,
- wind speed,
- ...

S is a region of interest. X(s),  $s \in S$  random variable at each location  $s \Rightarrow$  spatial process  $(X(s))_{s \in S}$ ,

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Spatial processes

#### Stationary spatial processes:

$$(X(s_1),\ldots,X(s_k)) \stackrel{\mathcal{L}}{=} (X(s_1+h),\ldots,X(s_k+h))$$

for any  $s_i \in S$ ,  $i = 1, \ldots, k$  and h with  $s_i + h \in S$ .

Statistical methods based on the  $\lambda\text{-madogram}$  00000000

Spatial processes

Stationary spatial processes:

 $(X(s_1),\ldots,X(s_k)) \stackrel{\mathcal{L}}{=} (X(s_1+h),\ldots,X(s_k+h))$ 

for any  $s_i \in S$ , i = 1, ..., k and h with  $s_i + h \in S$ .

In the Gaussian case, the dependence structure, is caracterised by the covariogram:  $Cov(X(s), X(s+h)) = \gamma(h)$ , depends only on ||h|| in the isotropic case.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda$ -madogram

Conclusion

Extreme spatial processes

# Max-stable spatial processes

Gaussian processes not well suited for e.g. rainfall, wind...  $\Rightarrow$  max-stable processes, unit Fréchet margins, dependence structure given by the exponent measure function V, that is:

$$\mathbb{P}(X(s) \leq x) = e^{-\frac{1}{x}}, \ \mathbb{P}(X(s) \leq x_1, X(t) \leq x_2) = \exp(-V_{s,t}(x_1, x_2)).$$

V is homogeneous of degree -1. The process is isotropic if  $V_{s,t}(x_1, x_2)$  depends only on h = ||t - s||. Max-stable processes have been defined by De Haan (1984).

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  00000000

Conclusion

Extreme spatial processes

# Max-stable spatial processes

Gaussian processes not well suited for e.g. rainfall, wind...  $\Rightarrow$  max-stable processes, unit Fréchet margins, dependence structure given by the exponent measure function V, that is:

$$\mathbb{P}(X(s) \leq x) = e^{-\frac{1}{x}}, \ \mathbb{P}(X(s) \leq x_1, X(t) \leq x_2) = \exp(-V_{s,t}(x_1, x_2)).$$

V is homogeneous of degree -1.

The process is isotropic if  $V_{s,t}(x_1, x_2)$  depends only on h = ||t - s||. Max-stable processes have been defined by De Haan (1984).

Spectral representation (De Haan):

 $X(s) = \max_{i \ge 1} W_i(s)/\xi_i,$ 

where  $\{\xi_i, i \ge 1\}$  is an i.i.d unit rate Poisson point process on  $(0, \infty)$  and  $\{W_i, i \ge 1\}$  are i.i.d copies of a positive random field W, independent of  $\xi_i$ .

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  00000000

Conclusion

Extreme spatial processes

# Max-stable spatial processes

Gaussian processes not well suited for e.g. rainfall, wind...  $\Rightarrow$  max-stable processes, unit Fréchet margins, dependence structure given by the exponent measure function V, that is:

$$\mathbb{P}(X(s) \leq x) = e^{-\frac{1}{x}}, \ \mathbb{P}(X(s) \leq x_1, X(t) \leq x_2) = \exp(-V_{s,t}(x_1, x_2)).$$

V is homogeneous of degree -1. The process is isotropic if  $V_{s,t}(x_1, x_2)$  depends only on h = ||t - s||. Max-stable processes have been defined by De Haan (1984).

Max-stable processes are Asymptotically Dependent in the sense that either X(s) and X(s + h) are independent or

$$\chi(h) = \lim_{u\to 1} \mathbb{P}\big(F(X(s)) > u | F(X(s+h)) > u\big) > 0.$$

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  00000000

Conclusion

Extreme spatial processes

# Max-stable spatial processes

Gaussian processes not well suited for e.g. rainfall, wind...  $\Rightarrow$  max-stable processes, unit Fréchet margins, dependence structure given by the exponent measure function V, that is:

$$\mathbb{P}(X(s) \leq x) = e^{-\frac{1}{x}}, \ \mathbb{P}(X(s) \leq x_1, X(t) \leq x_2) = \exp(-V_{s,t}(x_1, x_2)).$$

*V* is homogeneous of degree -1. The process is isotropic if  $V_{s,t}(x_1, x_2)$  depends only on h = ||t - s||. Max-stable processes have been defined by De Haan (1984).

Max-stable processes are Asymptotically Dependent in the sense that either X(s) and X(s + h) are independent or

$$\chi(h) = \lim_{u\to 1} \mathbb{P}\big(F(X(s)) > u | F(X(s+h)) > u\big) > 0.$$

Our purpose:

Semi / non-parametric estimations for models allowing various dependence structures.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

Extreme spatial processes

# Multivariate distribution function

The multivariate distribution function of a max-stable process X has following expression:

$$\mathbb{P}(X(s_1) \le x_1, ..., X(s_k) \le x_k) = \exp\{-V(x_1, ..., x_k)\},\$$

where V is called the exponent measure and homogeneous of order -1.

The density function writes in terms of the derivatives of V.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda$ -madogram

Conclusion

イロン 不通 とうせい マヨン しゅうろう

13/48

Extreme spatial processes

# Extreme coefficient

For any pair (X(s), X(s + h)), the bivariate distribution function satisfies for any x > 0:

$$\mathbb{P}ig(X(s) \leq x, X(s+h) \leq xig) = \exp\{-\Theta(h)/x\},$$

where,  $\Theta(h) = V(1,1) \in [1,2]$  is the Extremal coefficient function introduced in Schlather and Tawn (2002).  $\Theta$  is related to the  $\chi$  function:

$$\chi(h)=2-\Theta(h).$$

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

Extreme spatial processes

# Examples of max-stable processes I.

#### Smith (1990) Model

$$V_h(x_1, x_2) = \frac{1}{x_1} \Phi\left(\frac{\tau(h)}{2} + \frac{1}{\tau(h)} \log \frac{x_2}{x_1}\right) + \frac{1}{x_2} \Phi\left(\frac{\tau(h)}{2} + \frac{1}{\tau(h)} \log \frac{x_1}{x_2}\right);$$

 $\tau(h) = \sqrt{h^T \Sigma^{-1} h}$  and  $\Phi(\cdot)$  the standard normal cumulative distribution function.

#### Schlather (2002) Model

$$V_h(x_1, x_2) = \frac{1}{2} \left( \frac{1}{x_1} + \frac{1}{x_2} \right) \left[ 1 + \sqrt{1 - 2(\rho(h) + 1) \frac{x_1 x_2}{(x_1 + x_2)^2}} \right].$$

+ parametric models for  $\rho$ .

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

Extreme spatial processes

#### Examples of max-stables processes II.

Extremal-t process proposed in Opitz (2013) and Ribatet & Sedki (2013)

$$\begin{aligned} V_h(x_1, x_2) &= \\ \frac{1}{x_1} T_{\nu+1} \left( \alpha \rho(h) + \alpha \left( \frac{x_2}{x_1} \right)^{1/\nu} \right) + \frac{1}{x_2} T_{\nu+1} \left( \alpha \rho(h) + \alpha \left( \frac{x_1}{x_2} \right)^{1/\nu} \right) \end{aligned}$$

where  $T_v$  is the Student distribution with v degrees of freedom and  $\alpha(h) = [v + 1/\{1 - \rho^2(h)\}]^{1/2}$ .

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  00000000

Conclusion

Extreme spatial processes

#### Inverse max-stable processes

Let X' be a max-stable process as above, consider

$$X(s) = g(X'(s)) = -rac{1}{\log\{1 - e^{-1/X'(s)}\}} \quad s \in \mathcal{S}.$$

X is called inverse max-stable process, defined by Ledford and Tawn (1996). It has unit Fréchet margin and its bivariate survivor function satisfies:

$$\mathbb{P}(X(s_1) > x_1, X(s+h) > x_2) = \exp\big(-V_h(g(x_1), g(x_2))\big).$$

Inverse max-stable processes are Asymptotically Independent in the sense that  $\chi(h) = 0$  for any h. The exponent measure of X' is called the exponent measure of X and denoted  $V_X$ . The extremal coefficient of X' is called the extremal coefficient of X and denoted  $\Theta_X$ .

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Extreme spatial processes

#### Max-mixture processes

Wadsworth and Tawn (1997) proposed to mix max-stable and inverse max-stable processes, studied also by Bacro *et al.* (2016): Let X be a max-stable process, with exponent measure function  $V_h^X$ . Let Y be an inverse max-stable process with and exponent measure function  $V_h^Y$ . Let  $a \in [0, 1]$  and define

$$Z(s) = \max\{aX(s), (1-a)Y(s)\}, \quad s \in \mathcal{S}.$$

Max-stable and max-mixture processes ○○○○○○●○ Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

The  $\lambda$  madogram

# Definition of the $\lambda$ -madogram

When Gaussian processes are involved, the variogram is a useful and widely used tool:

$$\gamma(h) = rac{1}{2} \operatorname{var}(X(s) - X(s+h)).$$

The processes that we are studying have Fréchet marginal laws  $\implies$  no finite variance. The  $\lambda$ -madogram, proposed e.g. in Cooley *et al.* is used instead: for  $\lambda > 0$ ,

$$u_{\lambda}(h) = rac{1}{2}\mathbb{E}(|F^{\lambda}(X(s+h)) - F^{\lambda}(X(s))|),$$

where F is the unit Fréchet distribution function (so that  $F(X(s)) \sim U([0,1]))$ .

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

The  $\lambda$  madogram

# $\lambda$ -madogram for max-mixture processes

#### Property

Let X be a max-stable process, with extremal coefficient function  $\Theta_X(h)$ , and Y be an inverted max-stable process with extremal coefficient function  $\Theta_Y(h)$ . Let  $a \in [0,1]$  and  $Z = \max(aX, (1-a)Y)$ . Then, the  $F^{\lambda}$ -madogram of the spatial max-mixture process Z(s) is given by

$$\nu_{\lambda}(h) = \frac{\lambda}{1+\lambda} - \frac{2\lambda}{a(\Theta_{X}(h)-1)+1+\lambda} + \frac{\lambda}{a\Theta_{X}(h)+\lambda} - \frac{\lambda\Theta_{Y}(h)}{(1-a)\Theta_{Y}(h)+a\Theta_{X}(h)+\lambda} \times \beta\left(\frac{a\Theta_{X}(h)+\lambda}{1-a},\Theta_{Y}(h)\right).$$

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda$ -madogram

Conclusion

#### Least squared methods

We consider 
$$Z_i, i = 1, ..., N$$
 copies of  $Z$ ,

$$\begin{split} \widetilde{Q}_i(h,\lambda) &= \frac{1}{2} |F^{\lambda}(Z_i(s)) - F^{\lambda}(Z_i(s+h))|, \\ Q_i(h,\lambda) &= \frac{1}{2} |\widehat{F}^{\lambda}(Z_i(s)) - \widehat{F}^{\lambda}(Z_i(s+h))|, \end{split}$$

where  $\widehat{F}$  denotes the empirical distribution function (or any consistent estimator of the distribution function F). We have  $\mathbb{E}[\widetilde{Q}_i(h, \lambda)] = \nu_{\lambda}(h)$ . We shall estimate either

- the parameters of the max-mixture model (for a given model) or
- give non parametric estimations of Θ<sub>X</sub>(h), Θ<sub>Y</sub>(h) and provide a decision criterium for the parameter a.

It will be based on the minimization of

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda$ -madogram  $\bullet \circ \circ \circ \circ \circ \circ \circ$ 

Conclusion

Estimation of the parameters

# Parametric max-mixture models

 $Z = \max(aX, (1-a)Y) \implies$  chose a model for X and for Y. Recall that the bivariate distribution function is given by

$$e^{-aV_h^X(z_1,z_2)} \bigg[ e^{rac{-(1-a)}{z_1}} + e^{rac{-(1-a)}{z_2}} - 1 + e^{-V_h^Y(g_a(z_1),g_a(z_2))} \bigg].$$

You may also write a formula for all the finite dimensional joint distribution functions  $\implies$  theoretically you may compute the density function but it is practically untracktable, so that maximum likelihood estimation is not an option.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$  0000000

Conclusion

Estimation of the parameters

# Estimation of parameters

Method usually used (developped by Padoan *et al.* (2010)) : Maximum Composite Likelihood Estimation. The composite likelihood is the product of the pairwise likelihood. Then the parameter estimation is done by maximizing

$$\ell_N = \sum_{(s_k, s_j)} \sum_{i=1}^N \log f(Z_i(s_k), Z_i(s_j)) \Longrightarrow \widehat{\psi}_L,$$

where  $Z_i$ , i = 1, ..., N are independent (or  $\alpha$ -mixing) copies of Z, observed at locations  $s_k$ , k = 1, ..., M.

Conclusion

Estimation of the parameters

# Estimation of parameters

Method usually used (developped by Padoan *et al.* (2010)) : Maximum Composite Likelihood Estimation. The composite likelihood is the product of the pairwise likelihood. Then the parameter estimation is done by maximizing

$$\ell_N = \sum_{(s_k,s_j)} \sum_{i=1}^N \log f(Z_i(s_k), Z_i(s_j)) \Longrightarrow \widehat{\psi}_L,$$

where  $Z_i$ , i = 1, ..., N are independent (or  $\alpha$ -mixing) copies of Z, observed at locations  $s_k$ , k = 1, ..., M.

Adjust several models and retain the one with the smallest CLIC:

$$\mathsf{CLIC} = -2\left(\ell_{N}(\widehat{\psi}_{L}) - tr[\mathcal{J}(\widehat{\psi}_{L})\mathcal{H}^{-1}(\widehat{\psi}_{L})]\right)$$

where  $\mathcal{H}$  is the sensitivity matrix and  $\mathcal{J}$  is the variability matrix. Both intervene in the asymptotic variance of the estimator.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$   $\circ \bullet \circ \circ \circ \circ \circ \circ$ 

Conclusion

Estimation of the parameters

# Estimation of parameters

Alternatively, we propose to minimize the squared madogram difference:

$$\mathcal{L}_N = \sum_h \sum_{\|s_k - s_j\| = h} \sum_{i=1}^N (Q_i(h, 1) - \nu(h))^2 \Longrightarrow \widehat{\psi}_M.$$

Consistency of the estimators, under additional identifiability assumption.

Max-stable and max-mixture processes

Statistical methods based on the  $\lambda\text{-madogram}$   $\circ \bullet \circ \circ \circ \circ \circ \circ$ 

Conclusion

Estimation of the parameters

# Estimation of parameters

Alternatively, we propose to minimize the squared madogram difference:

$$\mathcal{L}_N = \sum_h \sum_{\|s_k - s_j\| = h} \sum_{i=1}^N \left( Q_i(h, 1) - \nu(h) \right)^2 \Longrightarrow \widehat{\psi}_M.$$

Consistency of the estimators, under additional identifiability assumption.

Adjust several models and retain the one with the smallest selection criterium:

$$\mathsf{SC} = \log \mathcal{L}_N + rac{2k(k+1)}{(N-k-1)}$$

where k is the number of parameters in the model.

Selection criterium for the mixing coefficient a

# Prediction with non parametric estimation

Compare the estimations of  $\mathbb{P}(Z(s^*) > z | Z(s) > z)$  by adjusting a parametric model vs the non parametric estimations of a,  $\Theta_X$  and  $\Theta_Y$ .

$$\mathbb{P}[Z(s_0^*) > z | Z(s_0) > z] = \frac{1 - 2e^{-\frac{1}{z}} + e^{-\frac{a\Theta_X(h_0)}{z}} \left\{ -1 + 2e^{-\frac{1-a}{z}} + \left[1 - e^{-\frac{1-a}{z}}\right]^{\Theta_Y(h_0)} \right\}}{1 - e^{-\frac{1}{z}}}$$

Where  $h_0 = ||s_0^* - s_0||$ .

- Importance of the dependence structure for spatial processes.
- The  $\lambda$ -madogram captures the main dependence informations of max-mixture processes.
- We have used it as an alternative to composite likelihood estimation.
- It is also useful in model-free estimation.
- Our estimations are consistent.
- To Do Extension to spatio-temporal processes.
- To Do Asymptotic normallity of the estimators.
